Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Electrical Engineer.

A Weekly Review

OF

Theoretical and Applied Electricity.

VOLUME IX.—1890.

(January to June.)

NEW YORK:
The Electrical Engineer,
150 Broadway.

Alphabetical Index of Contents.

E denotes Editorials. **A** denotes Articles. ***A** denotes Illustrated Articles. **Ax** denotes Abstracts and Extracts.
N denotes News and Notes. **L. N** denotes Legal Notes. **T. N** denotes Trade Notes, Novelties and Mechanical Department.

PAGE.
Accumulator, a solid.... N 350
“ Laurent-Cely.... A 477
“ Marx.... N 363, L 435

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. IX. NEW YORK, JANUARY, 1890. No. 97

THE ELECTRIC LIGHT IN NEW YORK, JANUARY 1, 1890.

ON New Year's night perhaps one-tenth of the seven or eight thousand arc lamps in New York were in use; the rest were dangling uselessly in streets and stores whose darkness was feebly relieved by occasional gas jets; and this not the result of accident or mishap, but of two weeks' work by a corps of axemen, set upon the poles and wires by the municipal authorities. Yet the United States was the birthplace of commercial electric lighting, and New York claims to be the industrial, commercial and social capital of America. The wit of man could hardly invent a more grotesquely absurd situation. But it has come about by no invention or contrivance; it is simply a natural consummation of vicious methods of municipal government on the one hand and vicious methods of conducting a new industry on the other hand: the crisis has been reached in New York, rather than elsewhere, simply because New York *is* the industrial, commercial and social centre of the United States, and gives, therefore, the freeest scope for both the best and the worst American tendencies. The stress has come here, and so has the break. Nowhere else was there such a field for electric lighting. It was immediately occupied; lines, good, bad and indifferent—of the latter two classes for the most part—were hastily run in every direction, till with the telegraph and telephone lines they so filled the streets of the city that a hue and cry arose to "bury the wires." This was the politicians' opportunity. The outcome was the Subway Commission, afterward the Board of Electrical Control; wherein, to quote our own words, "a political hack, a theatre agent and a presumptuous young attorney were given charge of providing a great city—far exceeding all other cities in the scope and magnitude of its electric service—with a proper system of electric conductors." Given such a condition of the electric lines as prevailed three or four years ago and such a board of commissioners as were appointed to deal with it, and the last state of the city was sure to be worse than the first. The history of the board's activities and inactivities, its doings, undoings and not-doings, is a mere weariness. Every one competent to understand the situation saw that the greater portion of the electric light conductors must remain above ground for years. The electric lighting companies soon got the measure of the commissioners, and not only kept their old and defective lines in operation, but went on building more, largely of the same flimsy construction and poor or no insulation, till at the beginning of the axemen's campaign, two weeks ago, there were several times as many miles of electric light wires overhead as there were when the legislature created a commission to put all wires underground forthwith. Excepting the low tension lines of the Edison company, laid by the company itself in its own way, no electric light conductors worth mentioning have been put underground and successfully operated in New York.

Until a year ago the Board of Electrical Control made no serious attempt to have existing overhead lines put in safe condition nor to prescribe rules for the proper construction and insulation of the numerous new lines constantly building. Then, when they undertook to apply the fairly adequate rules and regulations for overhead electric light wires, prepared by Dr. Wheeler, and notified the lighting companies of their violations of the rules, the companies gave little heed, and it was found that the Board of Electrical Control had no power to enforce its rules, and could only invoke the commands of the Mayor and the services of the Department of Public Works for the removal of lines defective under the rules and regulations. Now it is almost certain that a very little judicious chopping down of poles and cutting of wires last winter by the city authorities would have impelled the companies to such a general overhauling and improvement of their lines as would have prevented the recent series of fatalities, and would thus have precluded the wholesale and passionate onslaught of the past fortnight. The one pressing necessity was to make the overhead wires safe, an entirely feasible thing to accomplish, though troublesome and somewhat costly. But if either the authorities or the public ever had any faith in the competency of the Board of Electrical Control it had been dissipated by that body's ridiculous career; so its rules and regulations, together with its efforts to enforce them through the Department of Public Works, went unheeded till October last, when under the pressure of newspaper and popular clamor, the Mayor gave orders to the Commissioner of Public Works to remove from the streets such wires as were not safe under the rules of the board, only to be checked before the work had begun by the injunction of Judge Andrews in behalf of the lighting companies. A further series of fatal accidents from the wires followed in quick succession, continuing till the Supreme Court set aside the injunction; whereupon the axemen of the Department of Public Works were let loose. They have done their work under the guidance of inspectors of the Board of Electrical Control, and have now taken down about one-fourth of the mileage of electric light wires in the city. As the demolition included, in many cases, condemned portions only of long circuits, the result is to stop the service of about nine-tenths of all the arc lights in the city. In the opinion of the expert of the board, Dr. Wheeler, a condition of public safety has now been reached and he has advised a halt, which, we understand, has been ordered. Thus this city has accomplished the feat, after four years trial, of regulating a great industry and public service by destroying it.

What for the future? Arc lighting cannot be indefinitely suspended in New York. For public thoroughfares and many interiors it has become practically a necessity. It has never been shown that a general underground distribution by any system yet tried here can be conducted with greater safety to life than by a properly constructed overhead system. The numerous fatal accidents of the last few months are due to defects in lines or apparatus, remediable by the application of sound principles in the laying out, construction and insulation of lines, and of proper safeguards to apparatus and lamps. The neglect of such principles and safeguards has brought forth its fruit of disaster in such large measure here, rather than elsewhere, because of a great accumulation of lighting circuits in close proximity to each other and to a network of other electric wires, with the consequent liability of contact between neighboring conductors, for the most part poorly insulated, and nearly always devoid of an adequate protection, outside the insulation, against abrasion.

That the entire electric service of the city will ultimately be distributed underground we have no doubt—not for considerations of safety to life and property, but for considerations of public convenience and taste, and, in a long look ahead, considerations of economy—but no subway methods yet undertaken will, in our judgment, achieve that result. Any system adequate to the purpose has, in large part, yet to be devised, and, when devised and approved by trial, many years must elapse before it can be comprehensively applied.

Meantime the city must have its electric lighting. The present deadlock calls for a fresh start. Obviously the indispensable preliminary is to get rid of Messrs. Hess, Moss and Gibbens, permitting those worthies to resume their regular and more appropriate vocations. Public opinion, as well as the recent Grand Jury of the city will thank the legislature for so much as a beginning. If they then give us a board or commission composed in part of electrical engineers of unquestioned ability and repute, and, for the rest, of prominent citizens of administrative skill, and interested less in local politics than in the welfare of the city, giving them authority and power to regulate the existing electric service and to devise or select an adequate system of electric lines for the future, there will be some prospect of redeeming the present disgraceful situation, and much hope for the years to come. The past four years will not then have been altogether wasted.

THE ELECTRIC LIGHT CONVENTION IN FEBRUARY.

The Annual Meeting and Eleventh Convention of the National Electric Light Association will be held at Kansas City, February 11–14. One day more than usual is assigned to the meeting in view of the important topics to be dealt with and the extensive programme of papers to be read. The sound of the last fall of the gavel at the Niagara Falls convention last summer had not died away before Mr. E. R. Weeks, the president of the association, had begun preparations for the February meeting. With what assiduity and with what success he has worked, with the co-operation of the secretary and executive committee, can be seen in the programme for the forthcoming convention, printed elsewhere in this issue.

It is to be counted a distinct gain and advance in the scope of the association's proceedings that a distinctively scientific electrician, Professor Henry A. Rowland, has engaged to make an address in which he will treat practical difficulties from the point of view of the most advanced knowledge.

Another striking feature of the convention will be found in papers to be read by Professor Elihu Thomson and Mr. F. J. Sprague, and an address from Mr. T. A. Edison by phonograph. Mr. Weeks and the association are to be congratulated upon securing the co-operation of men of such technical eminence. Other papers, on technical and administrative subjects, entrusted to competent hands, together with reports of committees upon some of the most important and pressing questions touching electric light and power interests, make up a programme that should attract to Kansas City a larger gathering than any previous convention has shown.

The assembling of the association at Kansas City may be expected to bring out a larger interest in its work than heretofore among electric light men west of the Mississippi, and to induce a considerable accession to its membership.

Through the careful forethought of Mr. Weeks and the open-handed public spirit of Kansas City, the most ample and convenient accommodations for the sessions of the convention and for the accompanying electrical exhibits have been secured.

A LAWYER'S VIEW OF THE EDISON DECISION IN CANADA.

In a private note to the editor of the Electrical Engineer, a distinguished New York lawyer, who has been counsel in a number of the most important patent cases of recent years, referring to the decision of Deputy-Commissioner of Patents, Pope, of Canada, in February last, annulling the Edison lamp patent, and the reversal of that judgment on re-hearing by the Commissioner and the Minister of Justice, in November, remarks:—

> The interpretation put by Mr. Pope upon the facts was entirely destructive of all conservative principles of jurisprudence: and a short series of such decisions would unsettle all established things. I never saw a stronger instance of the inefficiency of a lay mind for dealing with topics whose significance the trained faculty easily perceives.
>
> There is the electrician's instinct, and the lawyer's instinct, which are like additional faculties—additional to the limited list given by nature to the rest of us. Just so medical evidence is quite different from legal evidence; and I suppose that most lawyers would be unable to feel the intuitive or reasoning process by which the physician or physicist reach sound judgments in their specialty.

In the Kemmler case the Supreme Court, General Term, finding the electrical execution law not repugnant to the constitution of the State of New York, has dismissed the writ of habeas corpus, and at last the sentimental philanthropists and officious medico-legalists who concocted and promoted the scheme will have the pleasure of seeing it put into operation.

A scientific observer of the recent tests of the electrical outfit at Sing Sing is reported to have said that to set up such elaborate machinery to kill a man was "like putting up a saw-mill to rip a match."

ARTICLES.

DATA AND PLOTS OF VARIOUS INCANDESCENT LAMPS TOGETHER WITH AN IMPROVED METHOD OF TESTING.

BY WM. L. PUFFER.

SINCE the appearance of the report of the Franklin Institute on incandescent lamps in 1885, there have been no published measurements either of the efficiency or of the distribution of light about the best-known lamps now in the market. But the market lamps of to-day are much better than those of 1885, so much so in fact, that the Franklin Institute data, although very valuable as showing the state of the art in 1885 are of no especial value for use with the lamps now manufactured.

The following data and curves have been calculated and plotted from the observations made by Messrs. Walter G. Whitmore and Edwin R. Pearson, class of 1887, Massachusetts Institute of Technology, who took as the subject of their graduating thesis "A Study of the Efficiency of Incandescent Lamps." The method used is substantially like that of the Franklin Institute, but I have changed and improved the method of plotting so that the five plots tell the distribution of light, shape of filament and its position in regard to photometer, etc. This method of testing lamps is in regular use in the laboratory with very satisfactory results.

The standard of light used is a Methven screen which has been standardized by comparison with many standard candles at different times and by different observers, and also with a Harcourt standard burner. The mean of a large number of observations agrees so closely with the maker's value of two candles that this is assumed to be right within the limits of error of the photometer, and no correction is used.

The photometer is a modified Bunsen, 100 inches long, graduated into inches and tenths by a dividing engine, and having also a scale of "ratios" which when multiplied by the candle-power of the standard give candle-powers directly. Both the standard burner and the lamp under test are thoroughly screened so that little if any diffused light reaches the eye of the observer. A key near the observer's hand and a lamp overhead furnish light when needed for reading.

The lamp-holder is quite different from that used by the Franklin Institute, and will hold any of the lamps now in the market without danger of straining. The socket with lamp under test is screwed on the end of a brass rod, which is free to slide or rotate in a sleeve fixed in the centre of and perpendicular to a disc of brass. Set screws are provided for clamping the rod in the sleeve. The disc is arranged on the bottom of a U-shaped strap in such a position that it can be turned while the rod always remains parallel to the sides of the U and in the same plane. The disc has notches every five degrees, and the strap carries a locking pawl, which also serves as an index.

The U-shaped strap is pivoted near the top in a frame so as to have rotation about a horizontal axis; it also has a notched disc, and the frame a pawl and index. One arm of the U is longer than the other, and carries a movable counterweight.

This apparatus is set with the horizontal axis perpendicular to the line of the photometer and on a level with the centre of the greased disc; the vertical circle being adjusted to read 0° when the lamp stands vertical with the socket underneath, then the horizontal disc is placed at 0° and the rod carrying the lamp moved till the plane of the shanks is perpendicular to the line of the photometer and the horizontal axis cuts the filament midway of its length. This position of the lamp is called the "standard position," and the photometer reading for this position, the "standard reading." By means of the horizontal circle, any desired degree of longitude can be instantly turned towards the photometer and by the vertical circle any degree of latitude. Flexible wires connected directly to the socket are used for current leads, and another set is used for measuring the potential at the lamp terminals. It is assumed that the socket and the lamp terminals will be of the same potential, except with very low resistance lamps, or with lamps requiring a large current.

Electrical measurements were made by a set of carefully calibrated Thomson's current and potential galvanometers, placed in a room free from magnetic disturbances, where the value of the earth's component had been determined. As the current taken by the potential galvanometer bears a very sensible ratio to that in the lamp, the instrument is always kept in circuit and a correction is made for the current passing through it. An adjustable resistance in the lamp circuit enabled the observer to keep the potential at the right amount. The potential galvanometer used was adjusted for Rayleigh volts, and as the difference between this and Legal volts is nearly within the limits of accuracy of the instrument no correction for reduction to the latter was made. It was assumed that the voltage marked on the lamps was in Legal volts, and that if the lamp changed its resistance while under test the volts must remain constant and the current and candle-power allowed to vary. If any lamps were marked in terms of the B. A. volts, then they were tested at too high a voltage.

When the lamp had been placed in the "standard position" and the potential adjusted, candle-power readings were taken at 65 different positions; the value used for each position being the mean of three or four settings of the disc according to the method used by the observer.

The standard direction to which all others are referred, is a line perpendicular to the plane of the shanks of the filament and lying in the equator of the lamp. By equator is understood the line cut upon the glass globe of the lamp, when upright, by a horizontal plane half way up the filament. *Zero point or* 0° is the starting point for measuring the angular rotation of the lamp and is at the intersection of the standard direction and the equator.

Horizontal distribution is measured by candle-power readings at each 30° around the equator beginning and ending with 0° or the "standard direction." Of these 13 c. p. readings, the first and last should, of course, check.

Mean horizontal candle-power is the mean of the first 12 of these readings, the check reading being omitted.

Vertical distribution is measured on each of four complete meridians, *i. e.*, those of 0°, 45°, 90°, 135° on the equator. On each of these four circles candle-power readings are taken at every 30° (of latitude), beginning and ending with 0°, thus giving 13 readings, the first and last of which should check.

Standard reading is the mean of all readings in the direction of the zero point ("standard position"). It is an arbitrary position selected for convenience. By it and the "reduction factors" the candle-power (spherical or horizontal) may be determined under any given potential or current at any subsequent time by one reading. Great care should be taken in placing a lamp in this position, because in some lamps a very slight error would make a very considerable difference in the candle-power, and of course in the "factors." When a number of tests are to be made on any one type of lamp it is preferable to select a point on the horizontal circle in that part of the curve where the rate of change of candle-power is very small, and so avoid error due to hasty or imperfect setting of the lamp for the standard reading.

Mean spherical candle-power is computed from 38 readings selected from those described, with the aim of obtaining the average intensity of light in all directions. These readings are as follows :—

Mean of 4 north pole readings (long. 0°, 45°, 90°, 135°) counts 1
Longitude 0°, Latitude 60°, 120°, 240°, 300°, giving 4
" 90°, " 60°, 120°, 240°, 300°, " 4
" 0°, " 30°, 150°, 210°, 330°, " 4
" 45°, " 30°, 150°, 210°, 330°, " 4
" 90°, " 30°, 150°, 210°, 330°, " 4
" 135°, " 30°, 150°, 210°, 330°, " 4
Equator, 12 readings (or mean horizontal × 12) counts 12
South pole reading assumed zero and counts 1

Total 38

The values for these positions are selected, added and divided by 38.

Horizontal reduction factor is the mean horizontal candle-power divided by the standard reading.

Spherical reduction factor is the mean spherical candle-power divided by the standard reading.

The mean spherical candle-power divided by the mean horizontal candle-power gives a very useful factor which is not so much affected as the two above by a slight error in setting the lamp in the exact standard position. Inspection of the curve for the 70-volt Weston lamp will show that a very slight error would materially change both the horizontal and the spherical reduction factors, but would not alter the ratio of the two. Obviously the product of the standard reading taken at any time, and the reduction factors will give the horizontal or spherical candle-power without any other measurements.

The method of plotting the results of a test on a lamp is thought to be an improvement on the Franklin Institute method, and is designed to show at a glance,—

1. The distribution of light in five great circles. 2. The relative position of the lamp filament to the photometer at the zero of each circle. 3. The appearance of the filament as seen from the photometer disc at the zero of each circle. 4. The rated candle-power. 5. The mean spherical candle-power. 6. The mean horizontal candle-power. 7. A table of data.

For example, take the 70-volt Weston lamp. This lamp has a zig-zag filament of rectangular section twisted when mounted, which gives a very characteristic set of distribution curves.

On the horizontal plot we see the photometer bar represented by the black line on the left, and in the centre is the horizontal projection of the filament at the zero position, "with the plane of the shanks perpendicular to the line of the photometer bar" and also a drawing of the filament as seen from the photometer disc at the zero of the circle. The curve shows that the light is greatest at about 150° and 330°, and weakest at about 60° and 240°; now, according to the Philadelphia method, we could not tell why this is so, but a glance at the projected filament (and also the pictures of the filament seen at 0°, 45°, 90°, 135°) shows that in one case the sides and in the other the edges of the corrugations correspond with the highest and lowest photometer readings. This plot also shows that the mean spherical candle-power is nearly equal to the mean horizontal, but that neither are up to the rating of 16 c. p. under any reasonable assumption that can be made as to the meaning of that term. The observed candle-powers are indicated by the figures written near the intersection of the curve and the radii drawn 30° apart.

The next plot shows the distribution of light in a vertical plane passing through the zero of the horizontal circle. As before, the horizontal projection of the filament is seen in its position relative to the photometer bar at the zero of the circle, and a drawing of the filament as seen from the photometer at the zero position.

The next plot shows the distribution in a vertical plane passing through 45° on the horizontal circle. The projection of the filament shows that the divided plate and lamp was turned 45° right-handedly, thus bringing the 45° position on the horizontal plot towards the photometer. The diminished amount of light is due, as indicated by the sketch of the filament, to the presentation of the edges of the carbon to the photometer. The next two plots are taken in a similar way at 90° and 135° respectively on the horizontal circle.

The pictures of the filament were obtained by holding the lamp behind a plate of glass and before a bright lamp and tracing the shadow of the filament. The scale of plotting is, unless otherwise stated, 0.1 inch per candle, and the filaments are drawn "life size."

All of these lamps were bought in the winter of 1886–87 of supply companies in Boston, out of stock, and presumably could not in any way be picked lamps.

The Edison lamps had the copper-plated shanks, and are now (1889) known as the "old lamp." The Weston 110-volt lamp is not now in the market, and I believe was on sale for only a short time after these were bought, an improved lamp taking its place. I do not know whether the 70-volt Weston lamp of the kind tested is in the market or not. The Thomson-Houston and Swan lamps appear similar to those now in the market, and are, as far as I know, the same.

(*To be continued.*)

TRANSFORMERS.[1]

BY HARRIS J. RYAN.

The apparatus by means of which electrical energy of one form may be transformed to that of any other form, few engineers fail to appreciate.

So great have been the anticipated possibilities offered by the application of the modern transformer of alternate current energy that in most cases in our country especially has the transformer found immediate application, with but little thought or study of its exact performance. Much experimental work has been done by trial methods to the end that our manufacturers are able to supply transformers that answer for much that is desired practically with a commercial efficiency that can be made higher than is probably possible by any other transformer of energy.

In electrical engineering, as well as other branches of engineering for the broad application of one method or another, it is always of the highest importance that the cause and extent of every effect is thoroughly understood. with regard to the mutual action and interaction of all forces and materials in relation to themselves, or to energy of one form or another.

It was with a view of obtaining, so far as possible, a clear understanding of all phenomena that take place in the commercial transformer, that the work producing the results here set forth was undertaken. It has not been possible at this time to prepare a paper as complete as has been desired, and we trust that in the near future we may add more data to that which is here presented.

In the outstart of this paper it should be said that the results of the experiments that are here presented were wrought out jointly by Mr. Ernest Merritt, of the department of physics, Cornell University, and the writer. What we had in mind in the work was an accurate determination of the exact performance of the commercial transformer whereby one should be able to derive results and data that should enable all phases of the performances of transformers to be understood clearly, and that should show the requisite principle of proper design. It may be well to state briefly the general method we employed. A single 10-light transformer that had been made and supplied for commercial purposes for incandescent lighting with 1,000 volts in the primary and 50 volts in the secondary was selected as a sample for investigation. It probably represented fairly well the average commercial performance of transformers, and might therefore be said to embody, to a certain extent at least, proportions that have proven by experience and experiment to be best for the particular purpose for which it is supplied.

This transformer was operated under the same impressed E. M. F. supplied from the electric lighting plant in which it had been used for supplying incandescent lamps commercially. It was operated with its secondary open and the same closed through one lamp, five lamps, and 10 lamps, and under these several conditions the exact instantaneous values of the ever varying primary impressed E. M. F., primary current, and the E. M. F. at the terminals of the secondary were observed. Again under these several conditions the square roots of the mean squares of the above values and of the secondary current were also observed. Then with these observations, the dimensions and the details of the construction of the transformer, many of the facts and performances that the engineer is concerned with, is brought to light.

Naturally the first thing to be considered is the electrical measurements and how they were made. A point on the armature of an alternator always passes a fixed point in its circumference at a time corresponding to a definite value of the varying E. M. F. and current, alike, with regard to these quantities in the primary feeders, transformer, primary or secondary, etc., so long as the conditions remain constant. In our experiments, we were only concerned with the values of the E. M. F. impressed at the terminals of the primary, the primary current and the secondary E. M. F., then by changing the position of the fixed point relative to the machine, the rotating point of reference in the armature would pass the new position of the fixed point at corresponding different values for the primary E. M. F., primary current, and secondary E. M. F., with respect to themselves and the position of the armature.

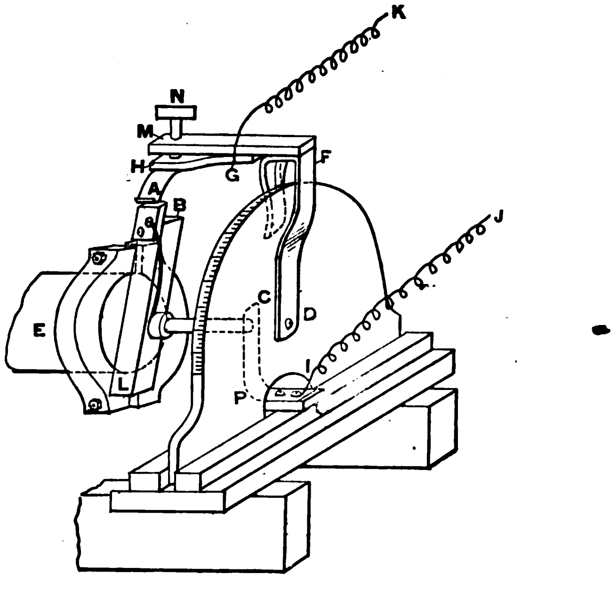

FIG. 1.

In figure 1, B, L, is a prism of hard rubber, bearing a projecting strip of brass, B, that on its upper side is filed to a dull edge. This edge is taken as a fixed point on the armature. An arm, F D, is arranged to rotate about D as a centre, a point that is in line with the axis of rotation of the armature. A semi-circular board of hard wood, attached rigidly to the dynamo frame, serves both as a support for this arm and a circumferential scale whereby the position of the arm may be observed relatively to the machine. The arm was made of brass and given the form shown in the figure. It was bent into a U shape at the top so as to pinch the board and thus remain fixed in any position desired. At the top of this arm is mounted a bar of hard rubber projecting toward the dynamo parallel to the armature axis. On its under side, fastened at G, is a brass strip, a tongue, H A, of spring brass is attached at the end and at right angles to the brass strip H G, as shown. The position of this part of the apparatus is carefully adjusted so that the point about which the arm rotates is in line with the axis of rotation of the armature and the sharply upward curved end of the tongue H A, just over the edge of the brass strip at B. Then when the armature is rotated the strip H G may be sprung inward radially by turning the thumb-screw N, until the tip of the tongue A is heard to just lightly touch the edge at B as it passes. The arm may then be adjusted by hand such that the tongue will touch the fixed edge on the armature at any desired phase of the primary E. M. F., primary current or secondary E. M. F. and current. Coaxial with the armature a small brass rod is mounted on the bar of hard rubber B L. It is connected metallically to B by means of a wire. At O, on the frame work supporting the semi-circular board, etc., is mounted another piece of hard rubber insulating and supporting the thin metallic strip, P C, that bears against the above brass rod. G and I then are the terminals of this commutating apparatus.

---

[1] A paper read before the American Institute of Electrical Engineers, New York, December 17, 1889.

In figure 2, E F is a non-inductive resistance in series with the primary of the transformer which is at work. At A is the apparatus described in figure 1, and E is an electrometer reading through a wide range.

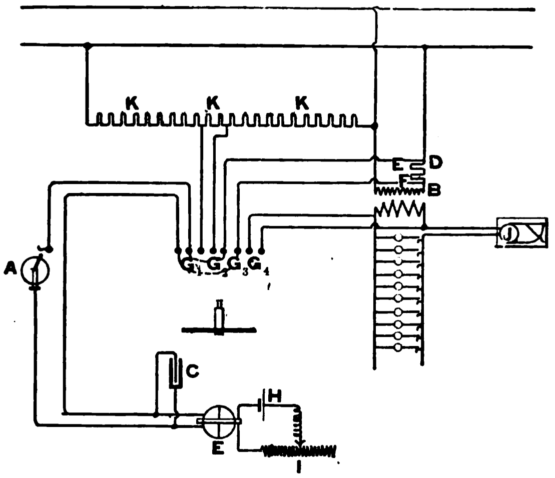

FIG. 2.

The terminals of the above non-inductive resistance and those of the electrometer are connected together through the commutating apparatus at A. Then it must be evident to all that the electrometer will become charged with a difference of potential equal to that existing between the terminals of the non-inductive resistance at the instant that the fixed edge on the armature passes the tip of the tongue in the apparatus at A. By reading the indications of the electrometer, therefore, and knowing the value of the non-inductive resistance E F, the value of the primary current corresponding to the particular phase due to the position of the arm in the apparatus at A becomes known. In a similar manner the primary and secondary E. M. F. are observed by changing the connections accordingly at G^1, G^2, G^3, G^4. Then the arm is rotated to another position, corresponding to a different phase, and the corresponding values of E. M. F.'s and current again observed as before. In this manner we proceed at equal intervals, sufficiently near, so that a curve may be determined by the values thus observed at the several intervals, such that the values of the E. M. F.'s or currents shall be accurately known at all times throughout a complete period.

A few words with regard to the electrometer at E, are not out of place here. It is the form that the writer devised especially for this and similar purposes. The essential features for an electrometer for these purposes are that it shall have the widest possible range through which it will read with accuracy. Its indications must be unvaried by the absolute potential to which it is subjected as a whole. Its law must be perfectly definite, and it is also desirable that its constant be unchanging.

Figure 3 illustrates this instrument in diagram. It consists essentially of cylindrical electrometer needle and quadrants E D. To the upper side of the electrometer needle is attached a magnetized steel mirror that acts as a magnet and as a mirror for observing the position of the same. The needle is hung by a single silk fibre, H, from a hook in the top of the case, as shown. Metallic contact from the needle to the case is made by means of a platinum wire, .0002 inches in diameter. This wire is readily provided in the desired form by using the platinum cored silver wire that is supplied by makers of surveying apparatus. It is cut the desired length, and hooks bent into shape at its terminals. By immersing all of it but the hooked terminals in nitric acid, the silver is dissolved away leaving the fine platinum core terminated by the two silver hooks. One end of this platinum wire thus prepared is linked into a hook into the top of the electrometer case and the other end into a small ring formed by a twist of the aluminum wire that surrounds the mirror C. The electrometer case is circular and the above needle and quadrants are arranged so that the magnetized mirror is at the centre of the case, and the needle and quadrants below it. About the case, as the figure indicates, is wound a coil, B B, of rather fine insulated copper wire. The magnetized mirror and this coil then, when the latter is in the magnetic meridian, constitute an arrangement similar to that of a tangent galvanometer. In the electrometer, the needle, case, and one set of quadrants are connected together and form one terminal and the other set of quadrants, being connected together, form the other terminal of the instrument, in the manner set forth in the diagram. Thus then, when the electrometer terminals are subjected to a difference of potential, the needle is acted upon by a couple brought about by the electrostatic forces and is deflected from its position of equilibrium. Then, as is shown in figure 2, current from a gravity cell in circuit with a suitable rheostat is sent through the coil on the electrometer in such a direction that the needle is brought toward its zero position by the action of the coil, carrying the current, on the magnetized mirror. The current is then further adjusted till the needle stands balanced at zero under the mutual action of the electrostatic and the electro-magnetic forces. Under such circumstances then the difference of potential is proportional to the square root of the current.

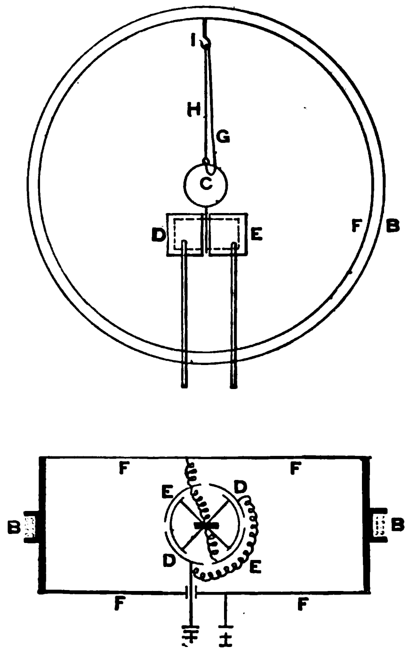

FIG.3.

If we can, as was the case when the measurements here presented were made, consider the E. M. F. of our cell constant, the difference of potential is likewise proportional to the square root of the reciprocal of the total resistance in circuit with the cell. Parallel readings, taken with a standard voltmeter throughout a range varying from 3 to 600 volts, gave identical results showing no deviation from the above law and an unvarying constant. On account of the metallic case and its connection to the rest of the apparatus, the indications of the electrometer are, so far as could be observed, entirely independent of the absolute potential to which it is subjected as a whole. In figure 2, when contact was made at A, and the electrometer charged to the potential difference to which its terminals were then subjected it was found that considerable of the charge was dissipated by leakage during the course of a revolution of the armature, no matter how good the insulation of the apparatus was. A one-half microfarad mica condenser was then placed in multiple arc with the terminals of the electrometer at C. Then after a few revolutions of the armature the condenser became charged to precisely the same difference of potential existing at the terminals of the electrometer D B, as shown in figure 2, when the rotating edge on the armature passed the tip of the tongue on the arm at A.

Under these circumstances the leakage that occurred was entirely unobservable as compared to the charge in the condenser during the course of time required for the armature to make many revolutions. Thus arranged then the electrometer would give accurate readings of the primary and secondary E. M. F.'s and primary current corresponding to the connection of its terminals and the position of the arm at A. Again, the square root of the mean square of any of these values could at any time be read from the electrometer by short-circuiting the apparatus at A, and cutting out the condenser at C. For the purpose of obtaining the curve of impressed E. M. F. and the $\sqrt{\text{mean}^2}$ of the same, twenty-two 50 volt lamps were put in series across the primary circuit. The $\sqrt{\text{mean}^2}$, of the impressed E. M. F. in the primary was then obtained by reading, by means of the electrometer with the condenser cut out and the commutating apparatus short circuited, the $\sqrt{\text{mean}^2}$ difference of potential existing between each set of two lamps. In this way 11 readings were obtained, the sum of which was the total impressed E. M. F. This served as a calibration of the non-inductive resistance formed by the lamps. At the same time that these observations were made, two lamps were determined upon to be used in all subsequent observations on the total E. M. F. The above observations served then as a calibration for the indications of the two lamps thus to be used. For the constant obtained by the ratio of the above total E. M. F. to the E. M. F. of these lamps taken at the same time always served to deduct the total $\sqrt{\text{mean}^2}$ or any particular value corresponding to a particular phase of the impressed primary E. M. F. when the same had been observed with regard to the two lamps in the group thus set apart. In this way we avoided the direct measurements of the total impressed E. M. F.

Two 50 volt lamps, E and F, were placed in series with the primary for a non-inductive resistance, and, as previously stated, the $\sqrt{\text{mean}^2}$, and the values corresponding to any particular phase of the fall of potential through these lamps were observed. This gave a measure of the $\sqrt{\text{mean}^2}$ or any particular value corresponding to a particular phase of the primary current, when the resistance of these lamps was known at the temperatures to which they were brought by the current. A curve of resistance corresponding to the range of currents through which we used these lamps was determined carefully by Mr. Merritt, at the Cornell magnetic observatory.

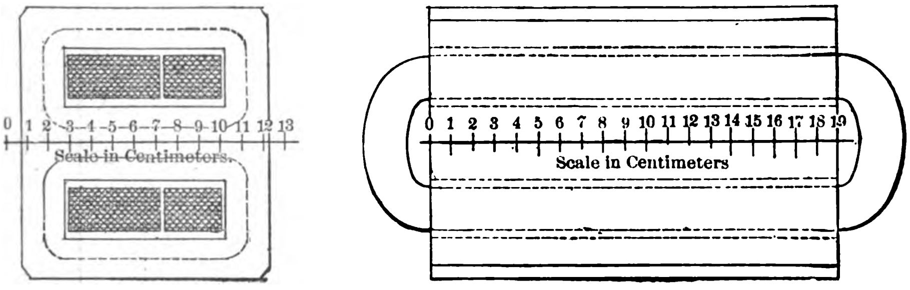

FIG. 4.

In series with the secondary circuit was placed a gravity ammeter containing a few small turns, and correct in its adjustment. It indicated the $\sqrt{\text{mean}^2}$ in the same way that an electro-dynamometer would have done. The observing of the various values of the secondary E. M. F. required no special arrangement,—this was done direct in all cases. Since the secondary was always at work on a circuit possessing almost no inductance, no determinations of the curve of secondary current were made, for it would be found to be so nearly in unison with the secondary E. M. F. and possess all the characteristic variations of the same. The $\sqrt{\text{mean}^2}$ of its value was always known from the indications of the ammeter. As a load for the transformer ten 16 c. p. 50 volt lamps were provided that could be turned on and off as desired, and they were at an average distance from the transformer of not more than five feet.

G^1, G^2, G^3, G^4, represent, in figure 2, the various terminals conveniently arranged on a switch-board for ready adjustment for any desired set of connections. The adjustable resistance at I, consisted of a plug resistance box, enabling one to get any number of ohms in circuit from 100,000 down. It was very conveniently arranged ; but a suitable slide rheostat and a damped magnet on the electrometer needle would have greatly facilitated the rapidity with which observations could be taken. The mode of procedure was to set the brush at some suitable point of starting out, then corresponding to this point readings of the instantaneous values of primary E. M. F. were made. When lamps were turned on in the secondary, the ammeter in that circuit was also read. The brush was then moved forward to a new position and the above readings repeated. This was continued until we had gone over a complete period of two alternations, then the $\sqrt{\text{mean}^2}$ readings of the primary and secondary E. M. F.'s and primary current were made. To do this required a period of time covering usually not more than two and one-half hours. Careful observations were made which showed that the insertion of one, two, or three lamps in the primary circuit *did not perceptibly change the relation* of the primary E. M. F. and current and secondary E. M. F. The indications of the ammeter gave data for correcting for variations of the speed of the dynamo, that throughout was not great.

The following data should be given with regard to the transformer that was used by us :—

Number of turns in the primary coil..........	675.
" " " secondary coil........	35.
Resistance of the primary..................	21.8 ohms.
Resistance of the secondary..................	.04 "

Figure 4 is furnished with a scale to which it was drawn, so that from it any details as to dimensions of the transformer can be obtained.

The iron discs of the magnetic circuit of the transformer were made one-half millimeter in thickness, and its surface merely oxidized, so that no special insulating material was provided between the laminations. The total volume of laminated iron used in the transformer was 2,050 cubic cms.

The mean cross-section of the magnetic circuit was 63.3 square cms., and the mean length of the magnetic circuit 30.8 cms.

The following observations with the secondary on open circuit and working on one lamp, five lamps, and 10 lamps were made and have been plotted in figures 5, 6, 7 and 8. The corresponding curves located by them, drawn in by the scales designated.

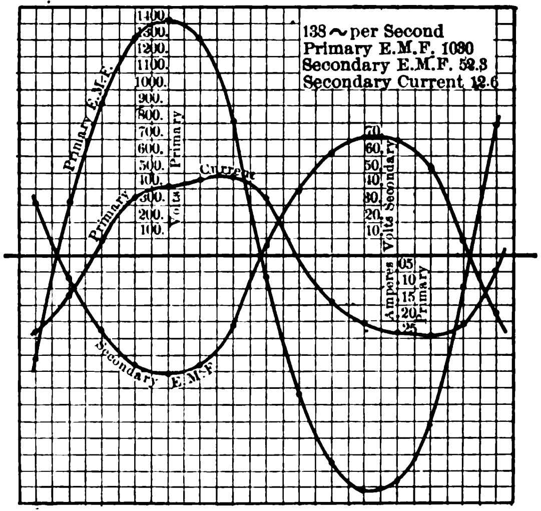

FIG. 7.

In figure 9 are plotted curves deduced from the foregoing observations, that show clearly the rate at which energy is given to the transformer, or that the transformer restores to the circuit at all points of a complete alternation for the several conditions under which the transformer was operated. The curves themselves show so clearly this particular part of the performance of the transformer that nothing more need be said about them, except to give the percentages of the work given to the transformer that is restored to the circuit by it under the several foregoing conditions :—

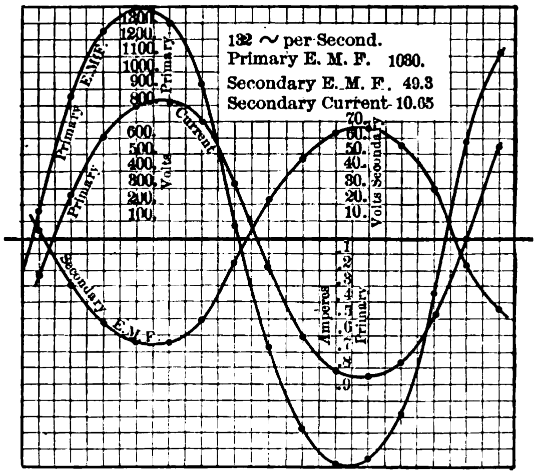

FIG. 8.

Open circuit	6.8%
One lamp	3.9%
Five lamps	.96%
10 lamps	.36%

The above observations and data are ample wherewith to compute the various losses of energy that take place in the transformer under the several loads and under no load, and the deduction of the corresponding efficiencies. These values have been computed and are given in the following table.

Proper corrections have been applied for the two lamps in series with the primary of the transformer.

Secondary E.M.F.*		Primary watts.	Secondary watts.	Efficiency.	Total loss in watts.	Hyster. loss in watts.	Heating loss. Primary watts.	Heating loss. Secondary watts.
Primary	10.20							
Second'ry, open	52.3	96.1	0.0	0.0	96.1	95.7	0.4	0.0
One lamp	52.3	159.1	64.3	41.1%	94.8	93.9	0.9	0.0
Five lamps	50.1	388.6	300.9	77.5%	87.7	83.1	3.3	1.3
10 lamps	47.5	607.9	525.0	86.6%	82.9	69.7	8.7	4.5

In figure 10 these values have been plotted to scales there indicated, and the respective curves that they determine have been drawn so that one can plainly see the exact performance of the transformer under all loads.

It is interesting to note that this transformer might be loaded to twice its rated capacity and the heating of the coils would still be less than that of the iron, although the heat produced by the iron grows less as the load comes on. Likewise, that its efficiency would not yet have reached its maximum and that it would have a value of 92 per cent. In figure 10 the outer curve represents the relation between the magnetizing current in the primary and the degree of magnetization for all points of a complete cycle. The values locating the curve expressing this relation were readily deduced from the observations made when the transformer was working on open circuit. In figure 5 the dotted curve represents the curve of primary current that would be found, should Foucault currents be known to be absent, and the relation of ampere turns and magnetization be the same going up as coming down. Then if Foucault currents were present the dotted curve would have a component at a quarter of a period in advance. This would produce a negative lag in the dotted curve. From the position of the actual primary current, it is plainly seen that but a very small component of the above nature is possible, and that the energy that is wasted by eddy currents must therefore be small. The radical departure of the primary exciting current from the approximate sinuous variation of the primary impressed E. M. F. is plainly brought out to be due to *hysteresis*. From the preceding consideration it is also evident that almost the entire advance of the exciting current and, therefore, the corresponding dissipation of energy, is due to the same cause.

It was thought of much interest to see what amount of hysteresis should be indicated by carrying the transformer slowly through the same cycle of magnetization that it went at the rate of 138 cycles per second when at work on the circuit with its secondary open. Accordingly, by Ewing's method modified for the purpose by Dr. Sumpner, Mr. Merritt determined the inner curve shown in figure 10. We regret greatly not to have had time for a careful redetermination of this inner curve, and carry the magnetization to the same maxima that was done in the transformer when on the circuit. The agreement between the cards would have been more marked even than in figure 10.

The assumption made by Mr. Swinburne in his remarkable and valuable paper on the "Design of Transformers" (proceedings of the British Association, 1889), would, therefore, be fully substantiated. Mr. Mordey's experiments, in which *hysteresis* and *Foucault current* losses producing a common loss were determined, were performed by cycles of magnetization produced by rotation in which the degree of magnetization did not vary in amount but direction, and cannot be said to throw light on the correctness of Mr. Swinburne's assumption. Some, commenting on this paper, have used Mr. Mordey's results as evidence that these assumptions are wrong.

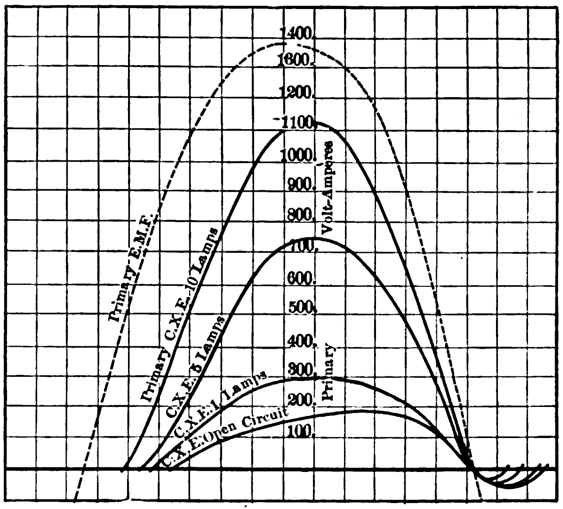

FIG. 9.

By a knowledge then of the magnetic properties of the iron, with which a given transformer is to be built, and the methods made use of by Mr. Swinburne, its efficiency is something that can be correctly predetermined.

The importance of making a transformer produce the same E. M. F. at the terminals of the secondary under all loads, asserts itself when it is used for incandescent lighting. In the transformer, under consideration from the ratios of the primary and secondary turns, the E. M. F.'s that they produced, and the variations of magnetization that had to take place through the primary, in order that the same should produce an E. M. F. equal and opposite to that of the primary impressed E. M. F., the magnetization produced through the secondary and the magnetization set up about the primary in its own air space are determined. In the present transformer this "leakage" of magnetism amounted to about 1.2 per cent. When the transformer works on full load 4.5 times as much current passes through the primary, and the "leakage" of the primary in its own space is 4.5 times as much as on open circuit and becomes 5.4 per cent. This value, together with the small drop due to the actual resistances of the transformer coils, accounts for the fall of 3.5 volts that was observed by turning on all of the ten lamps.

---

*The values given in this column have not been corrected for the two lamps in series with the primary for the first three conditions and the one lamp that was used for the last. With 10 lamps, where one lamp was used in the primary this correction amounts to an increase of the secondary E. M. F. of three per cent. On open circuit and one lamp it is negligible and three per cent. increase for five lamps. When this correction is applied the drop of 3.5 volts obtained is what was observed by direct measurement on the secondary.

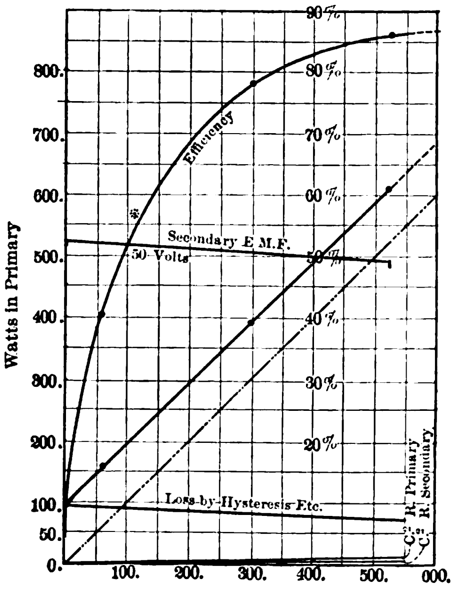

FIG. 10.

Attention might be called to a similar "leakage" in magnetism that takes place in the secondary circuit. It is plainly brought out in figure 8 by the lag of the secondary E.M.F. This magnetic "leakage" producing a self-induction is proportional to the secondary current. The rate of change of this quantity then is proportional to the E. M. F. that it produces. This E. M. F. is, therefore, a quarter of a period behind the secondary current, and results in producing a small lag in primary and secondary currents and secondary E. M. F.

Finally, there is a curious behavior of this transformer that remains to be accounted for. This is the considerable decrease in the loss of hysteresis as the transformer is loaded down, that is not to be accounted for by rise of temperature or the falling off of the magnetization due to the increased "leakage" about the primary in its own air space.

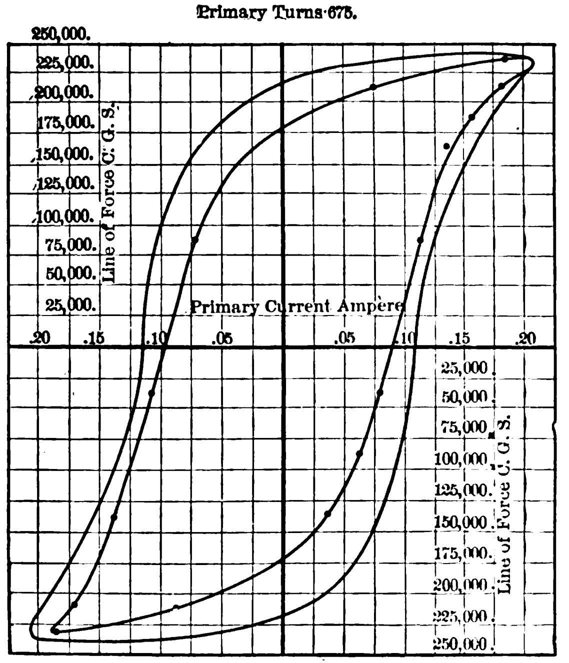

FIG. 11.

The following reason suggested itself to the writer, why this should take place :—

Mechanical shock has been shown to greatly reduce loss by hysteresis when iron is passed through cycles of magnetization. Since the currents are at all times opposite each other in the two coils of a transformer, strong repulsion occurs when these currents are at a maximum and no force is exerted when they pass through zero. So it follows that they continually keep thrusting each other apart when at work and add to the disturbance of the laminated iron that already exists on account of its changing magnetization. This increasing of the mechanical vibration of the iron, may therefore account for the above-mentioned phenomenon.

On open circuit the maximum magnetization of the iron per square cm. was 3,850 C. G. S.

Loss by hysteresis per cycle per cubic cm., neglecting Foucault currents, .046 watts at 138 ∿ per second.

Coercive force per centimeter of the iron, 2.76 C. G. S.

In conclusion, the writer would say that the data here given show for themselves so clearly the advisability of providing some practical means for breaking the primary circuit of the transformer when not in use, that the strong advice of Mr. Swinburne in concluding his paper need not be repeated.

A NEW VIEW OF TELEPHONE INDUCTION.[1]

One of the most peculiar developments connected with the introduction of the telephone was the presence of remarkable sounds, which were heard when the telephone line was of any considerable length. Sometimes it sounded as though myriads of birds flew twittering by ; again, sounds like the rustling of leaves and the croaking of frogs could plainly be heard ; at other times, the noise resembled the hissing of steam and the boiling of water. Even a display of Aurora Borealis causes powerful currents in the telephone. Some of these disturbances have been more or less satisfactorily accounted for by assuming differences of potential at the two ends of the line ; by the sudden heating or cooling of the line ; and by the passage of electrified bodies of air or clouds. Another very curious effect was observed when the first two telephone wires were run parallel to each other on the same cross-arm for the distance of even a few miles ; it was found that, although the insulation of the lines was high, a conversation carried on over one wire could plainly be heard on its neighbor. This overhearing is commonly called "cross-talk." As the number of telephone wires increased, and their bunching together in cables became necessary, it was found that, in addition to the cross-talk, there was another element of trouble added, which was due to the electrostatic effect of the cable, and caused the voice to be transmitted in an indistinct and muffled manner. This evil exists to such an extent that where cables are used the speaking limit is soon reached. While a study of the strange noises heard in the telephone might be of interest, I shall in this paper limit myself to the consideration of cross-talk and to the action which takes place when wires are bunched in cables. In the simple case of inductive cross-talk first cited, in which two telephone wires are strung parallel on the same cross-arm, the presence of cross-talk is said to be due to dynamic or current induction—that is, if a current commences to flow in one of the wires from north to south, it will at that instant cause an induced current to flow in the other wire in the opposite direction, from south to north. As the telephone current is constantly changing its direction and strength, this explanation seems to apply and is the one given in the text-books. This is the kind of induction referred to in the law of Lenz, and applies to induction coils and to parallel wires when the current is of sufficient strength. I shall speak of this hereafter as electro-magnetic induction. I shall now describe some experiments which seem to prove that the induction between telephone wires is due to electrostatic rather than to electro-magnetic action. I will first show a case of electrostatic induction between telephone wires in which there is a neutral point at the centre of the secondary wire, at which point there is no induction, while at the ends marked inductive effects are noticeable.

---

[1] Paper read November 21st, 1889, by Mr. John J. Carty, electrician of the Metropolitan Telephone and Telegraph Co., New York, before the New York Electric Club.

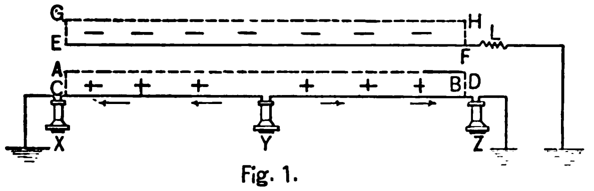

Fig. 1.

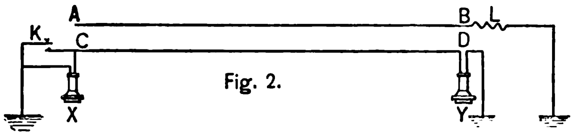

Fig. 2.

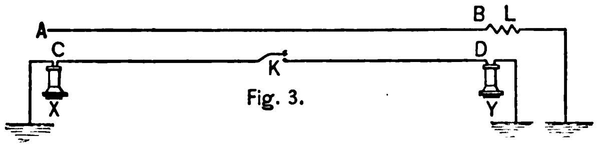

Fig. 3.

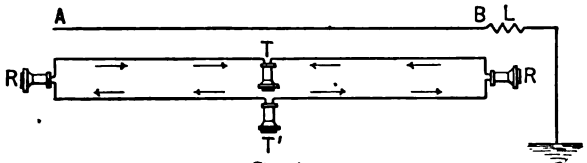

Fig. 4.

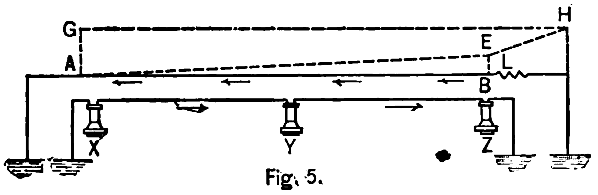

Fig. 5.

In figure 1, E F and C D are two well-insulated parallel telephone wires, each 200 feet long, and placed one-eighth of an inch apart. E F is open at one end and connected to ground at the other through a Blake transmitter, L, in the ordinary manner. In front of the Blake transmitter I place a vibrating tuning fork, which acts on the transmitter in the same manner as the voice, and which produces impulses on the line E F of the same strength as voice currents. At the centre of the line C D we have the telephone Y, and at the extreme ends the telephones X and Z. With the tuning fork at L in operation, tones are heard at X and Z, but the middle telephone Y is silent. A study of the changes of potential produced in the wire E F by the transmitter will give us an explanation of this phenomenon. As is well known, the telephone current is an alternating one, and the potential of the line E F varies constantly, and is changed from positive to negative many times per second. The wire E F being open at E would be at the same potential throughout. It is assumed that at a given instant the height of potential at F would be represented by the dotted line F H; then the potential at E would be represented by the dotted line E G, and the total charge on E F would be represented by the rectangle E G H F. We will assume that this charge is of the minus sign. The existence of this charge on E F presupposes the presence of a charge of opposite sign on C D, which would be represented by the rectangle A C D B. Now, suppose the potential on E F becomes zero, owing to the operation of the transmitter, then the whole charge on E F gets to earth at the grounded end of E F; but the charge on C D has two paths to earth, one at C and the other at D. This results in two currents, as shown by the arrows, one flowing to earth through the telephone X and producing sound at X, and the other flowing to earth through the telephone Z and producing sound at Z. No current flows through the telephone Y, and consequently no sound is produced therein. Again changing the potential at E F causes a corresponding set of currents, but in opposite directions to those first described, meeting in the centre and producing no sound in the centre telephone, but causing the end telephones to give out sounds the same as in the first instance. Inasmuch as the line E F is opened at one end, and therefore has almost an infinite resistance, it is clear that this phenomenon is purely an electrostatic one. In this and the succeeding experiments I have not attempted to give the exact shape of the induced charge, as it would unnecessarily complicate the subject and would not in any way affect the result. As a matter of fact, the dotted line A B should slope off from the centre toward the ends. With the line E F grounded through an ordinary subscriber's line and instrument, the effect is the same as when the line is open, and the neutral point is still found. This is because the telephone current, even when flowing in a close circuit, is so weak that it is not capable of producing a magnetic field of sufficient strength to affect the neighboring wire, or the magnetic effect is so small that it is obliterated by the movement of the static charge. For convenience in some of the succeeding experiments, the disturbing wire will be shown open at one end. If there is no current flowing at the neutral point, opening the wire at that point should have no effect on the telephones located at the ends. In figure 3 A B is the disturbing wire with the transmitter L arranged as before; K is a key located at the neutral point of C D. With the transmitter L in operation, no change is produced in the tones heard at the telephones X and Y by opening and closing the key K. If this induction were electro-magnetic, opening the line C D would prevent current from flowing in any part of the circuit. In figure 2 we have another proof of the electrostatic nature of telephone induction. A B is the usual disturbing wire with its transmitter L. C D is the secondary wire with the telephones X and Y located at the ends, as in the previous experiment. By means of the key K the telephone X may be cut in and out of the circuit. With the key open the usual tones are heard at X and Y. Now, if the induced current flowing in the circuit C D is due to electro-magnetic induction, upon short circuiting the telephone X and thereby reducing the resistance of the circuit C D the strength of the induced current should be increased and the tone at the telephone Y should be correspondingly louder. But this is not the case, as on closing the key the sound at Y instead of being increased, entirely disappears. This is because the charge on the wire C D finds an easy path to earth through the key, and such a small portion of the charge goes to earth through the telephone Y that no audible effect is produced therein.

Figure 4 shows the disturbing wire A B arranged as before, but the secondary wire, instead of being put to earth at both ends, has its circuit completed by a second wire placed outside of the field of A B. With this arrangement neutral points are found at T and T^1, while the usual disturbances are heard at telephones R and R^1, located at the ends. In this case, a movement of the static charge takes place in the metallic circuit, causing at one moment a set of currents starting from T^1 in both directions through the end telephones and meeting at T, and at the next instant the reverse takes place. I will now show some of the effects of electro-magnetic induction, at the same time suppressing electro-static induction.

In figure 5, A B is the disturbing wire as before, but grounded through a short thick wire at A. Instead of placing the tuning fork in front of the transmitter L, and acting on it through the air, producing delicate currents like voice currents, an automatic circuit breaker and five cells of Leclanché battery were connected in the primary circuit of the transmitter, thus producing in the line A B alternating currents of great strength. The secondary wire containing the telephones X, Y and Z, is of the same length, and at the same distance from the disturbing wire, as in the previous experiments. With the circuit breaker at L in operation loud musical tones are heard at X, Y and Z, and the tone is the same in all three telephones, the neutral point in this case having disappeared. This is a true case of electro-magnetic induction, because short circuiting the telephone Y increases the sound in the remaining telephones, and leaving the short circuit on Y and short circuiting the telephone X still further increases the sound at Z. This latter experiment furnishes a most striking contrast to the result obtained in figure 2, where, by short circuiting the telephone X, the sound was completely removed from the telephone at the other end of the line. Another proof that this is electro-magnetic induction, is found in the fact that if the line be opened at Y the sound disappears from all the telephones. If the line A B were opened at A, the potential along the line would be constant, and the charge which A B would take would be represented by the rectangle A G H D, but when the line is grounded at A through a low resistance, there is, of course, a fall of potential along A B; the principal drop, however, occurring in the secondary coil of the transmitter L, the line B E representing the height of potential at the terminal of the coil, and the electro-static effect which the line A B would have is represented by the triangle A E B. This triangle, although exaggerated in the diagram, is still much smaller than the rectangle A G H D, and explains the absence of electrostatic induction between the wires, while the powerful current generated in L, and the comparatively low resistance through which it has to flow, accounts fully for the electro-magnetic effects observed. I have made a large number of laboratory experiments and observations on actual telephone lines, all of which point strongly to the conclusion that electro-magnetic induction does not exist in telephone lines outside of the telephone and transmitter. This view of the subject, applied to the theory of transpositions of metallic circuits and to the action of wires in cables, gives the only satisfactory explanation of observed phenomena.

Now, we come to the important question: Can this electrostatic induction be prevented? In answer to this, it can be said that the cross-talk due to electrostatic induction can be eliminated by properly constructed metallic circuits. But there still remains the muffling effect referred to in the first part of this paper. This is sometimes called "electrostatic retardation," and comes in wherever two telephone conductors are run close to each other for any great distance. Where telephone wires are strung upon poles and are at a distance of a foot or more from each other, this action is very small, but where they are bunched together in cables, a hundred or more within a two-inch pipe, it is very great. It is a curious fact, however, that the amount of this trouble, other things being equal, depends on the character of the insulating medium or dielectric, as it is called, but is independent of its specific insulation resistance, the induction being less when air is used as an insulator than with any other substance among the materials adopted in practice. Dry cotton, paper, and silk rank next to air in this respect, but when gutta-percha or any of the rubber compounds are used the induction is much greater than with the other materials mentioned. This peculiar property of an insulator—*i. e.*, the facility with which it allows induction to take place through it—is called its "specific inductive capacity." In the present state of things, then, the only way to overcome electrostatic retardation, after having an insulator or dielectric of the lowest specific inductive capacity, is to increase the distance between telephone conductors. It is evident that in underground systems this distance can never be great. In all of our large city underground systems the space which is allowed for each wire is 0.125 of an inch.

This putting of wires underground in cities is the only bar to a universal system of telephony; and if direct air lines were built, New York and Chicago would be placed within speaking distance of each other at once. To place telephone wires underground, and maintain the same efficiency as in overhead lines, would require an insulation on each wire of over 2 feet in thickness, and instead of getting 50 pairs of wires into a 3-inch pipe, as at present, a tunnel occupying half the street would be required for one cable alone. When we consider that a telephone office of even moderate size would require about a hundred such gigantic cables, it is seen how almost hopeless the case becomes. Most engineers think that this difficulty is inherent in the problem, and that the electrostatic action can only be overcome by separating the wires as already stated. In view of the recent researches tending to give us a deeper knowledge of the nature of electricity which have been conducted by Hertz and others, I think there is reason to hope that some other way out of the difficulty may be found. You are all, no doubt, familiar with those celebrated experiments wherein electrical undulations of many million times per second were produced, and, although they were transmitted along a conductor with the velocity of light, yet they followed each other with such rapidity that nodal points were produced, the location of which determined the length of the waves. These waves have been produced in various ways, and by means of large prisms of pitch and by metallic mirrors they have been refracted, focused, and reflected; in fact, they have been found to obey much the same laws as light waves. I think it must follow from these experiments that our disturbing wire A B is throwing off, laterally, waves of great length, and that these waves impinging upon the adjacent wire C D, produce the various inductive effects observed. Now, if by some means these waves could be deflected from their course and prevented from falling on the wire C D, it follows that there would be no disturbance whatever produced therein. We know that if these waves were of the same length as light waves, this action could be prevented by the interposition of a properly shaped lens of glass, or by a mirror; or if they were of the length used in Hertz's experiments a lens of pitch or a metallic mirror would have the same result. Now, although the telephone waves are of great length, it seems possible that by interposing a properly shaped dielectric or combination of dielectrics, that an interference or refraction might be produced which would have the desired result.

This electrostatic problem is one of the most important, and until within a year or two the least studied, and is at present the least understood of all the various difficulties with which we are confronted, and the reward which awaits its proper solution is greater than that which fell to the lot of the inventor of the telephone itself.

.... THERE is a clique of mathematical cooks who have axes of their own to grind; a clique who writes the electrical books, and who are very active in scientific societies, who are not satisfied simply to perform the functions nature has qualified them for doing, but they do their best to ignore those to whom they are indebted for the hares they cook and dress and eat.—*S. Alfred Varley.*

.... HOW inexplicably sometimes error flourishes, grows and maintains an apparently healthy appearance of truth, without having any root whatever.—*S. P. Langley.*

THE DANGERS OF ELECTRIC LIGHTING.[1]

A REPLY TO MR. EDISON. BY GEORGE WESTINGHOUSE, JR., PRESIDENT OF THE WESTINGHOUSE ELECTRIC CO.

No one will now question the great benefit of the electric light to the public. By the rays of the brilliant arc lamp our streets are better lighted than ever before, with a corresponding increase in security both to life and property, while the incandescent lamp supplies our homes with the most agreeable artificial illumination known to science, and one which, at the same time, is absolutely free from the deleterious products of combustion incident to the use of gas or oil.

The use of electricity for supplying light and power has now become as much a part of our every-day life as the railway, the steamship, the street car, or the gas supply. In fact, we live in a time when power is made in every way subservient to the comfort of the people. It is employed in nearly every useful industry, with a full knowledge that such employment has been and always must be attended with an appreciable degree of danger. Electricity is one manifestation of power. It represents a form of mechanical energy capable of being utilized for innumerable purposes. Indeed, were it a question of prohibiting the use not merely of electricity, but of all other things dangerous to life, we would no longer have fires to warm us or light to enable us to see, and, in fact, would be deprived of most of the necessaries and comforts of existence. As has been the case with the utilization of all other forms of energy, the demand for the most economical methods will ultimately prevail, provided these can be made safe, as they most certainly can, by the exercise of proper precautions.

Electric lighting, unlike many other industries protected by patents, has been followed with keen interest at every step by the public at large, but among more immediately interested parties the struggle for the control of the electric light and power business has never been exceeded in bitterness by any of the historical commercial controversies of a former day. Thousands of persons have large pecuniary interests at stake, and, as might be expected, many of them view this great subject solely from the standpoint of self-interest. That the public may to some extent understand the mass of literature now being printed with reference to the use of electric currents of both high and low tension, it is necessary that something of the story of this business rivalry should be told.

The successful use of the Jablochkoff electric light in Paris, in 1878, was the beginning of a new era in a field which had not remained wholly uncultivated during the preceding thirty years, although with unimportant commercial results. In 1877 and 1878 we find William E. Sawyer, Charles F. Brush, Hiram S. Maxim, Edward Weston, Thomas A. Edison, and others entering this alluring field of invention. In 1877 Sawyer took out three patents of more than ordinary importance, in view of what has since become the practice in electric lighting. Early in 1878 he associated with himself Albon Man, who became a joint inventor with him of several electric-lighting inventions, the promising results from which led to the formation, on July 8 of that year, of the Electro-Dynamic Light Co., of New York. The objects for which this company was formed were stated as follows:—

> The production of light and power by means of electricity; the lighting of streets, buildings, and other places; producing, conducting, and distributing electrical currents for lighting and other purposes, and the manufacture and sale of all machinery necessary for or adapted to accomplish the purposes named.

Charles F. Brush early invented and perfected a dynamo, an arc lamp, and a method of operation whereby a number of such arc lamps could be used on one circuit, principally for street lighting purposes. To make and sell Mr. Brush's inventions, there was organized the Brush Electric Light Co., of Cleveland, Ohio.

In September, 1878, appeared the first announcement of Mr. Edison's discoveries in electric lighting, and on October 17, three months after the formation of the Electro-Dynamic Co. to operate Sawyer and Man's electric light inventions, the Edison Electric Light Co., of New York, was organized. To introduce the inventions of Maxim and Weston, there was formed the United States Electric Lighting Co., of New York, and thus four large corporations were started almost simultaneously upon a career of competitive business. The energy and money since expended by each of these corporations in efforts to thwart the progress of the others has mutually embittered the interested parties to a degree that can with difficulty be comprehended by those not immediately concerned in the strife.

Mr. Edison, already a well-known inventor in telegraphy, apparently had his attention drawn to this subject by a visit to Mr. William Wallace, of Ansonia, Conn., in September, 1878. There he saw Mr. Wallace's dynamos feeding eight electric lights at one time, and also witnessed the transmission of power by electricity from the Naugatuck river, a quarter of a mile distant. The spirit in which he entered the electric light business would seem to be indicated in the following extract from the New York *Tribune* of September 28, 1878:—

> "Mr. Wallace's machines produce electricity which can be made available for electric light." Mr. Edison continued:—"I have let the other inventors get the start of me in this matter somewhat, because I have not given much attention to electric lights, but I believe I can catch up to them now." * * * "Now that I have a machine (Wallace's) to make the electricity, I can experiment as much as I please." "I think," he added, smiling, "there is where I can beat the other inventors, as I have so many facilities here for trying experiments." "If you can make the electric light supply the place of gas, you can easily make a great fortune," the reporter suggested. "I don't care so much for a fortune," Mr. Edison replied, "as I do for getting ahead of the other fellows."

Setting out with this determination, it is perhaps no wonder he has worked so energetically. Reviewing his inventions and utterances, it is evident that he believed from the beginning that the system of gas distribution was the thing to be copied, and that electric conductors could be laid under the streets with branches or connections to each house, supplied by generators located in central stations; but this system necessitated the limitation of the electric pressure to that which the lamps could be made to endure—in practice about 110 volts. The formidable quantities of copper required to conduct the necessary volume of current at this low pressure soon led to the development of what is known as the Edison "three-wire" system of distribution, an improvement founded upon earlier patents of Sawyer and Brush. This system permits a pressure of 220 volts on a circuit equipped with 110-volt lamps, and requires for the whole installation only one-quarter of the weight of copper conductors necessary with the two-wire system.

It must be constantly borne in mind that the pressure of this direct-current system is necessarily limited to 220 volts by the conditions of the lamp, and also that the underground mains in all directions are interconnected, forming what is termed a mesh-work, analogous to the gas-distribution system, but with very important differences, hereafter explained at length. The cost of copper required for mains of sufficient conductivity to avoid a decrease in light by reason of large consumption, even at moderate distances, was found to be prohibitive, and this fact necessitated a system of "feeders," through which the electricity is forced against a very considerable resistance. These feeders are connected at various points to the meshwork of mains so as to maintain at such points an approximately constant pressure. The generators at the central stations deliver their product collectively into common feeders and mains, and with a large plant an enormous energy is constantly exerted in these mains.

---

[1] From the *North American Review*, December, 1889.

Any plan of distribution involving the meshing of the mains underneath the streets, with all house wires connected directly thereto, is regarded by the majority of competent electrical engineers as in many respects radically defective; so defective, in fact, that, unless the use of alternating currents can be prohibited, it seems destined to be wholly supplanted by the more scientific and in all respects (so far as concerns the users or occupants of buildings) far safer inductive system. Apparently sensible of this, Mr. Edison does not hesitate to say:—"My personal desire would be to prohibit entirely the use of alternating currents."

The fact that the shocking accident which has given rise to the present discussion was, in all probability, the result of a direct continuous current, and that the burning of the unfortunate victim may have resulted from a low-tension current used for telegraphic or power purposes, apparently does not deter Mr. Edison from his self-imposed task of proving the low-pressure system to be the only safe one. It is, nevertheless, a common practice of the Edison company to use uninsulated overhead wires for its 220-volt current for the purpose of economizing first cost, although it is well known that such a current is capable of burning a body subjected to it as effectually as in the case of lineman Feeks, provided the skin be sufficiently abraded to diminish the electrical resistance of the subject.

Accepting Mr. Edison's classification of the currents used for electric lighting, let us discuss them as follows:—

> *First*—The low-tension continuous current, with a pressure not exceeding 200 volts, used for incandescent lighting.
>
> *Second*—The high-tension continuous current, with a pressure of 2,000 volts and over.
>
> *Third*—The high-tension semi-continuous, or pulsatory, current, with a pressure of 2,000 volts and over.
>
> *Fourth*—The alternating current, with a pressure of from 1,000 to 3,000 volts and over.

The first is not dangerous when a person comes into momentary contact with one wire, but no one can endure its passage through the body when the contact is made "in the most effective manner." I have witnessed the roasting of a large piece of fresh beef by a direct continuous current of less than one hundred volts within two minutes. Any one having access to electric lights operated by the low-tension underground system in New York can easily prove to his own satisfaction how much credence ought to be given to the assertion that a current of 200 volts can be passed through the human body without producing uncomfortable sensations. Let him connect a tin pan to one of the electric wires, and place therein a thick piece of beef, and upon this a gridiron of metal connected to the other wire. The electrical energy exhibited in the steaming and cooking of this beef may possibly surprise the experimenter. If the current is from an underground main, the experiment may be varied by connecting the gridiron to a water-pipe with like results. With even less than one hundred volts it is painful beyond endurance to press firmly with the hands the brushes or any bright brass work of the dynamo, or to grasp any metal connected with the wires.

That a continuous current of moderate tension may produce death when the connection is continued for even a short time is shown by the published record of experiments conducted by A. E. Kennelly at the Edison laboratory. With a continuous current of 400 volts a dog weighing fifty-seven and a half pounds was killed in forty seconds; and in another instance, with 1,000 volts of continuous current, a dog weighing thirteen and a half pounds was killed instantly. That an alternating current of one hundred volts, even when effectively applied, does not kill is shown by two experiments on another dog. A continuous current of 304 volts was applied for thirty seconds, and then an alternating current of one hundred volts for sixty-five seconds; yet the dog was unhurt. But mark this important fact; the so-called "alternating current" used for these experiments on animals was not the alternating current of commerce, but was an Edison direct continuous current made alternating by a "pole-changer," producing an effect incomparably more dangerous than the true alternating current under discussion, because of the exaggerated tension resulting from the partial discharge of the field magnets of the dynamos, which act in this case like a Ruhmkorf coil of enormous dimensions.

The power of destruction residing in the low-tension current under certain conditions is best illustrated by quoting from Mr. Edison's own article, where he says:—

> Near the corner of William and Wall streets, New York, the underground conductors of the Edison Illuminating Co. became crossed, and the current which was passing through them at a pressure of only one hundred and ten volts melted not only the wires, but several feet of iron tubing in which they were incased, and reduced the paving-stones within a radius of three or four feet to a molten mass.

He adds:—"This system is so arranged that consumers are not affected by such accidents as these." But it is, nevertheless, true that every consumer is directly connected to the mains, so that it is evident that the reverse of this statement would have more truly represented the actual possibilities of the case.

Concerning the three other conditions of current referred to by Mr. Edison, he classes them, and rightly so, as dangerous to life, although momentary contacts have repeatedly been made with wires carrying 1,000 and even 2,000 volts of each of these currents, without fatal results. In fact, there have been hundreds of cases in which momentary contact with an alternating current of 1,000 volts and over, as well as with pulsatory and continuous currents, has resulted only in painful shocks, unaccompanied by permanent injury.

The reader of Mr. Edison's article who is unfamiliar with the alternating system of distribution would naturally infer that in practice the same voltage is carried on the house wires as on the mains, as in the Edison system; but such is never the case under any circumstances. In this complete disconnection of the street and house wires is found the reason of the positive safety both to life and property enjoyed by the users of the alternating system. It is one of the great advantages of this system that it admits of the use of high voltages for the street mains, and of wholly separate and independent currents, with absolutely safe voltage, for all wires within buildings—a condition which is infallibly secured and maintained by converters, or transformers, located in or near each building. Each transformer of electric energy is composed of two separately-wound and insulated coils, one of thin wire connected to the street mains, and the other of thick wire connected to the wires of the building. One of the most beautiful features of the alternating system is that when currents of electricity are sent back and forth with almost inconceivable rapidity through the coil of thin wire, there is induced in a neighboring coil of thicker wire an equivalent amount of electrical energy, but at the same time so modified that the voltage, which may be 2,000 in the thin coil, need be only 50 in the thick coil, the volume of electricity being as many times increased as the pressure or voltage is diminished. A current of 50 volts is used in practice, as it is now well established that lamps of this capacity are far more durable and give a better light, with much greater economy, than the 100 or 110-volt lamps. The two coils being absolutely separated from each other by effective insulation through which the current in the primary wire cannot possibly penetrate, it follows that the alternating system has an enormous advantage over the direct system in respect of absolute safety to the consumer.

It seems possible that the time is not far distant when the regulations governing the distribution of electricity will rigidly prohibit direct electrical connection between the street wires and the local service wires inside houses, thereby excluding from dwelling places all the dangerous effects possible to ensue from accidental leakages in the underground system.

The forebodings of Mr. Edison concerning the results of the leakage of current from the underground mains have perhaps been in great part suggested by difficulties experienced in the working of his own system. The Edison underground lines are made up of a great number of short sections of iron pipe, each containing a copper rod, with a plastic insulating material forced between the copper and the iron. These sections are about sixteen feet long and are laid in trenches, and united at the joints like gas-pipes. These pipes are usually laid above the frost line, and are necessarily affected by changes of temperature, which cause the iron pipes to move at the joints. It is, therefore, not unusual to find that after a short time the electrical leakage becomes sufficient to light a number of lamps when connection is made between a water pipe and one of the mains—a fact well known to insurance inspectors. The Edison company continues to use this system, although cables are now made capable of withstanding 2,500 volts of either alternating or direct current with even greater security than Mr. Edison has been able to provide for the 220 volts employed in his low-tension system.

One of the most perfect cables of to-day is a copper wire covered with a thick insulation, over which lead is pressed with very great force, thereby expelling air and gases, and solidifying the insulating material between the lead and copper. There is then woven upon the lead a textile envelope saturated with a water and gas-proof compound. The continuous sections of this cable reach from one man-hole to another, a distance of several hundred feet, and can easily be drawn in and out of the ducts provided for them. Where one piece of cable is joined to another, an electric connection is made and well insulated, then encased in lead, which is afterward soldered to the ends of the respective cables. A cable of this character is uninfluenced by changes of temperature and is subject to little deterioration. To guard against its being pierced by a spark of static electricity, a very simple device is attached to it, offering an easier path for the electricity than through the insulation.

One of the differences alluded to, as existing between the low-tension, continuous-current underground system and a gas-pipe system, is that with reference to leakage.

A gas leak is local and incapable of producing effects at a distance. With electricity, however, the aggregate effects of all the leakages from an underground system may be suddenly concentrated at any point within that system, as by one of the house wires coming in contact with a metal pipe, and such a contact may result even from the work of a mouse; whereupon the leakage of the entire net-work, which may amount to a large percentage of the total current, will be concentrated, and the surrounding material affected (although perhaps to a less degree) in the manner described by Mr. Edison in the reference to the currents at the corner of William and Wall streets.

The interconnection of the conductors for the purpose of reducing the original investment has, in another important respect, a contrary effect from the meshing of gas mains. In the case of the latter, the fracture of a pipe at one place, while it may cause a considerable leak, does not necessarily extinguish the lights of all the consumers. The grounding of one of the wires of an underground circuit, however, affects the entire mesh-work; and a cross between the wires may extinguish the lights of an entire district for a considerable time.

As to the accidents from electric currents, the records of deaths in the City of New York show that there were killed by street cars during the year 1888, 64 persons; by omnibuses and wagons, 55; and by illuminating gas, 23; making the number killed by the electric current (5) insignificant compared with the deaths of individuals from any of the other causes named. The placing of the wires underground would eliminate many of the causes of accidents from electric currents, and they may all be prevented by the employment of reasonable and well-understood safeguards. Mr. Edison's statement that the putting of the wires underground will, instead of diminishing, increase the danger to life, is little less than amazing, at least when considered in connection with his advocacy of his own underground system. The repeated and violent explosions of gas in the man-holes of the Edison system, and in connection with the underground systems of the telephone and telegraph companies, have certainly shown that electricity from any source, either from low-tension electric light, telephone, or telegraph currents, either of which is capable of producing a spark, may be the cause of a serious catastrophe, although there is no doubt that the accumulation of explosive mixtures within these chambers can be effectually prevented. Inasmuch as Mr. Edison's arguments against underground wires generally are equally applicable to his own system, it would seem, logically, that, if his views are to prevail, all electric wires must cease to serve the public. The experience of the cities of Chicago and Philadelphia in the use of underground cables for high-tension currents, to say nothing of the large number of cables laid underground in Rome, Berlin, Milan, and in other cities, indicates that the success of properly-constructed underground systems, whether for currents of high or low tension, has been established beyond question.

There is one radical difference between the alternating and the continuous low-tension system which should be fully understood. It has been shown that in the alternating systems the street mains are absolutely disconnected and detached from the house mains, while the low-tension system necessitates the meshing of all underground mains into one net-work and the supply of the current to that system by a series of feeders. In fact, it necessitates at times the supply of an enormous electrical energy to supply the demand. With the alternating system the practice is not to mesh the wires, but to run independent pairs of wires connecting the switch-board in the station with the thin wires of the converters. These wires are designed to supply only about 1,500 to 2,000 lights per pair, and are made of such a size that there is no appreciable decrease in the lights at the farther end, even if there is a very large consumption of current. Each of these pairs of mains can, therefore, be provided at the station with safety devices which will instantly and automatically cut off the current in the event of a cross-connection taking an abnormal current from the dynamo. Such safety devices cannot be made available with the low-tension system.

Mr. Edison is, moreover, unfortunate in his reference to the use of electric currents abroad. Under the British Electric Lighting Act of 1888 the Board of Trade has issued a set of regulations. Concerning high-pressure conductors it says:—

> 9. *High pressure conductors to be insulated.* Every high-pressure aerial conductor must be continuously insulated with a durable and efficient material, to be approved by the Board of Trade, to a thickness of not less than one-tenth part of an inch, and in cases where the extreme difference of potential in the circuit exceeds 2,000 volts, the thickness of insulation must not be less in inches or parts of an inch than the number obtained by dividing the number expressing the volts by 20,000.

It will be seen that these regulations provide not merely for 2,000 volts, which is double that used in the American alternating system, but for any voltage whatsoever which the electric companies may desire to carry.

In a recent authorized publication it is stated that the main characteristics of the Edison system are as follows:—

> *First*—Subdivision of generating units to secure reliability and economy of production.
>
> *Second*—Meshing of distributing conductors in a common network throughout the entire area to be supplied, to secure uniform distribution.

Third—A system of special feeding conductors to apportion equally the supply of energy to the demand throughout the area covered by the system of conductors.

Fourth—A system of indicators to denote in the station variations of pressure at any point in the area of consumption.

Fifth—A system of regulation to compensate for any variation of pressure.

The main characteristics of the alternating system contrast with these in a marked manner. These characteristics may be stated as follows:—

First—Large generators located in central stations at points convenient for coal and water supply, and away from residences.

Second—A series of mains running from the station, each set of mains having a capacity of not exceeding 1,500 lights, and each pair of mains extending to the station, so that the lines are only interconnected at the switch-board in the station.

Third—By reason of the limitation of the number of lights on each circuit, the leakage on any one circuit is reduced to a minimum.

Fourth—The interruption or burning-out of any one circuit can have no effect upon other circuits, the contrary being a most serious defect in a system wherein the wires are meshed.

Fifth—Absence of numerous and costly regulating contrivances.

Sixth—Ability to use within all houses a 50-volt current, whereby the most efficient lamps can be utilized.

Seventh—Absolute separation of the street mains from the house mains, thereby preventing injury or danger from the leakage from the street mains.

Eighth—The use of a mechanical meter, which accurately records the entire electrical energy consumed in the house.

Ninth—The easy regulation of the current if required, so that the lights may be turned up and down without expensive and wasteful machinery.

There is not on record a solitary instance of a person having been injured or shocked from the consumers' current of an alternating system. This is wholly due to the fact that the converted current within the buildings supplied need not exceed 50 volts, and that the street mains and the house wires are absolutely detached from each other, so that there is no possibility of a shock being received from leakage or short-circuiting in the high-tension street mains.

The fire risk from electricity is the one most to be feared. With the continuous current, whenever there is occasion to put out a number of lights by the movement of a switch, it not infrequently happens that a dazzling arc of blue flame is formed which has to be blown out. With the alternating system it is impossible to form any considerable arc, even if the switch controls a thousand lights, the rapid reversals of the current having the effect of preventing its establishment.

Mr. Edison's observations concerning the efforts of his competitors in the direction of saving in investment are no less applicable to the desires of the suppliers of his own system. At the annual convention of the Edison Illuminating companies at Niagara, in August of this year, the following resolutions were offered by Mr. Gilbert, of the Detroit Edison station :—

Resolved, That the Association respectfully call to the attention of the Edison General Electric Co. the difficulties under which local companies are now laboring in consequence of the lack of

1. An efficient and inexpensive arc light system.
2. An arc lamp which can be economically operated on the three-wire system.
3. A flexible method of enlarging the territory which can be profitably covered from their stations for domestic lighting *by higher pressures* and consequently *less outlay of copper* than that involved by the three-wire method.

We earnestly appeal to the parent organization to supply these deficiencies.

The proceedings of the convention also contain the following:—

The address of Sir William Thomson, as president of the physical section of the British Association in 1882, contained this memorable passage:—"Nothing above 200 volts, on any account, ever should be admitted into a ship or house or other place where safeguards cannot be made absolutely and forever trustworthy against all possible accident." This opinion accords with what Mr. Edison has always maintained—that in the long run every system will fail which does not (for domestic service) use a low-pressure current.

This is precisely what the alternating system supplies. The successful use of arc lamps depends upon high voltages. Neither Mr. Edison nor any other person has yet been able to supply the requirements of the public by means of a low-tension arc lighting system.

A careful consideration of the whole subject proves that it is possible to light all the buildings within a city by means of electricity distributed by an underground system, wherein there shall be no connection whatever between the underground system and the wires within the buildings. It has been demonstrated that an incandescent lamp operated by a 50-volt current will give more light at a given cost than a 110-volt lamp; and, these two things being admitted, it follows that, if there are to be any restrictive regulations with reference to electric lighting, they might more properly be: *First*—That the electromotive force within any building shall never exceed 100 volts; *Second*—That no underground system shall be placed in electrical connection with the wires in the buildings; *Third*—That no underground system shall be permitted which does not provide for the renewal and repair of the mains without digging up the streets.

In conclusion, it is worthy of note that for three years past the purchasers of apparatus for electric lighting, who are at perfect liberty to buy from any company, have, for the most part, preferred to use the alternating system, so that to-day the extension of that system for central station incandescent lighting is at least five times as great as that of the direct current. If the opinion of these persons, who can have no interest except to purchase that which they believe to be the best, is of any value, then the alternating system has been demonstrated to be the one which can give to the public that which they so much desire—a safe, cheap, efficient, and universally applicable system of incandescent electric lighting.

POINTERS.

.... It is not so much what is received or earned, as what is saved of those earnings, which counts in the long run.—*C. C. Haskins.*

.... At the present time, with competent, careful and intelligent men in charge of central stations, there is absolutely no danger from the use of high-pressure currents that calls for any change from the present system.—*B. E. Sunny.*

.... The immediate demand in our large cities is for installations of hundreds of thousands of horse-power, instead of those of a few thousand horse-power merely.—*George Cutter.*

.... In my opinion, the true interests of science are suffering from the baneful influence of the government monopoly, which is not a monopoly of telegraphs simply but of electricity and science generally.—*S. Alfred Varley.*

.... It is not alone the larger expenditures which serve to dissipate and fritter away the receipts of any industry. There are numerous smaller expenses which, like the mice in the fable, gnaw many minute holes in the bin and cause large leaks in the aggregate.—*C. C. Haskins.*

.... The record outside of the City of New York, where proper methods have been adopted and a reasonable amount of room could be secured, has been practically free from electrical fatalities during the last three years.—*B. E. Sunny.*

.... More people were killed by teams in the streets of New York and Brooklyn in the last two years than have been killed by electric currents in the whole history of the world.—*George Cutter.*

.... What the mathematician has been doing for the most part has been simply examining and microscopically measuring, with mathematical spectacles, the edifices raised by the engineers of the earlier period. The nearest approach to anything original they can be credited with, is simply designing measuring instruments, and even in such work our mathematical men are much more indebted to the intelligent mechanic than they are disposed to admit.—*S. Alfred Varley.*

ABSTRACTS AND EXTRACTS.

COMPARISON OF THE INTRINSIC INTENSITY OF SOLAR RADIATION WITH THAT OF THE ELECTRIC ARC IN DIFFERENT PARTS OF THE SPECTRUM.

[Extract from a paper on "The Temperature of the Moon," by S. P. Langley, with the assistance of F. W. Very, in *American Journal of Science*, vol. xxxviii., December, 1889.]

This observation of the comparative intensity of the sun and the electric light is given in the original memoir only so far as to show that it brings independent evidence of a large atmospheric absorption of the extreme infra-red rays and enables us to estimate approximately the amount of this absorption at each point in the spectrum. The observations were not repeated to obtain such a thorough comparison as would be desirable. As they have never been printed, however, and since, as far as we know, none other such exist, we will give them here under the caution that they are to be considered only first approximations. The light was that from the pit of the positive carbon of gas coke, one inch in diameter, with the current derived from a dynamo, actuated by an engine of 10 h. p., and therefore certainly at least as intrinsically hot and bright as any smaller arc light in more common use, and presumably much more so. The apparatus was that already described in the memoir "On Hitherto Unrecognized Wavelengths." [See description of galvanometer below.]

The following table gives the observed galvanometer deflections after applying a multiplying factor for the shunt, which had to be used for the larger readings:—

1 Deviation rock salt 60° Prism.	2 Wave-length.	3 Observed deflection *sun* after absorption	4 Observed deflection *arc*.	5 Calculated deflection *sun* without absorption.	6 Observed ratio sun and arc.	7 Calculated ratio of unabsorbed sun and arc.
° ′	μ	div.	div.	div.		
43 53	0.373	7.5	1.3	34.	5.77	26.0
43 17	0.398	11.5	1.5	38.	7.67	21.8
41 54	0.489	33.5	5.3	60.	6.32	14.4
41 05	0.587	104.0	10.5	115.	9.90	11.1
40 45	0.663	204.0	22.0	204.	9.27	10.0
40 27	0.749	432.0	43.5	450.	9.93	9.1
40 05	0.96	1 073.0	215.0	1 763.	4.99	8.2
39 54	1.13	1 783.0	459.0	3 534.	3.88	7.7
39 20	2.87	1 905.0	882.0	5 645.	2.16	6.4
39 00	4.3	521.0	235.0	1 363.	2.22	5.8
38 45	5.6	75.0	157.0	832.	0.48	5.3
38 00	10.4	19.5	39.0	156.	0.50	4.0

The result of the comparison of the (of course, unabsorbed) electric arc with the radiation of the sun after absorption, as shown in the sixth column, is that this solar radiation in the orange and red is nearly ten times that of the arc, while towards the violet end of the spectrum, the relative superiority of the absorbed solar heat diminishes, evidently because of the progressive increase of the atmospheric absorption in that direction, which lessens the solar intensity without sensibly affecting that of the arc. The solar efficiency continues greater through all the infra-red spectrum known until very lately, while in the extreme portions recently investigated, it falls below that of the arc. This is partly due to the fact that radiation from a source at a lower temperature (the arc in this case) is relatively more powerful in the longer than in the shorter waves; yet it can hardly be doubted that here also (that is, in the *extreme* infra-red) a very large atmospheric absorption has taken place.

There is reason to believe that a considerable part of this absorption takes place in the first few meters of air, while we conclude, from all the evidence in our possession, that the real telluric absorption, being a locally selective one, is much greater than the comparison of high and low altitude observations alone would indicate.

The import of this comparison will be still more evident from a consideration of the seventh column, where by means of the Allegheny tables of the solar absorption, we have calculated the ratio of the arc heat to that of the sun before absorption by the earth's atmosphere. Although a large absorption by the solar atmosphere has already taken place, we see that in the ultra-violet the solar radiation is from 20 to 30 times that of the arc, while that of the absorbed sun is only about 6 or 7 times. When we reach the region of the red and upper infra-red, we see that these ratios are nearly the same in the absorbed and unabsorbed solar radiation, showing that the terrestrial absorption in this region (which was once supposed to be its principal seat), is in fact very small, while in the regions of the extreme infra-red corresponding to temperatures not greatly exceeding that of the terrestrial soil (regions only revealed by quite recent investigation) the telluric absorption again becomes considerable.

The general result of this comparison is to enhance our ideas as to the rate of solar radiation, and as to the solar temperature. Comparisons of the total solar radiation with the total arc radiation have (it may be observed) been made before, but so far as I am aware, comparisons of the heat in different portions of their spectra are here presented for the first time.

Description of Galvanometer Used by Professor Langley.

—From *American Journal of Science*, vol. xxxii., Aug., 1886.

It must be remembered that while the nominal sensitiveness of a galvanometer can be increased to any extent by increasing the astaticism of the needle (quite as nominal power can be multiplied to any extent on a telescope by altering lenses at the eyepiece), that the real or working capacity depends upon the ability to always obtain a like result under given conditions. Accordingly, we have continued to devote great pains to extend our original conception, so as to make the galvanometer, as well as the bolometer, not merely an indicator of heat, but a real "meter," which shall distinctly answer the question "how much?" as to almost infinitely minute amounts of energy.

For the benefit of any physicists who may desire to repeat these experiments, we may observe that we have found the bolometer capable of almost unlimited delicacy of perception of heat, but that our chief trouble has arisen from the difficulty of constructing a galvanometer suitable to develop its full capacity for exact measurement. We have been unable to find among galvanometers ordinarily constructed one capable of indicating with precision changes in the amount of current of much less than $\frac{1}{1000000}$ of an ampere. It was in the construction of a galvanometer, designed to measure the heat in the spectrum of the moon, that we acquired the experience which we have utilized in the present researches.

A reflecting galvanometer, of the form devised by Sir William Thomson, has been used for the basis of our construction, and altered as follows. (For several of the changes described I am indebted for suggestions due to the great kindness of Sir William Thomson and Professor Rowland.) First, the short suspending fibre supplied by the makers has been replaced by one 33 cm. in length, stretched and prepared with particular care. Next, since the effect of a given minute change of current is proportional (other things being equal) to the magnetic moment, and to the minuteness with which the angular deflection of the needle can be read, we have reconstructed the mirror and needles as follows: For the magnets,[1] soft sheet steel $\frac{1}{20}$ of a mm. thick, is rolled up into minute hollow cylinders each about 8 mm. long and about 1 mm. diameter. These are hardened and made to take a permanent charge of nearly 900 Gaussian units. Ten of these are placed behind the back of the mirror and ten below, making twenty in all. The reflecting mirror is accurately concave, being specially worked for the purpose, 9.5 mm. in diameter, 1 meter radius of curvature, weighing 63 milligrams, and platinized on the front face by the discharge *in vacuo* of platinum electrodes, through the process of Professor Wright,[2] of Yale College. The stem which unites the upper and lower system of the magnets is a hair-like and hollow tube of glass, while it occurred to me to replace the aluminum vane of the ordinary instruments, by the wings of a dragon fly (*Libellula*), in which nature offers a model of lightness and rigidity quite inimitable by art.

---

[1] The design and construction of the hollow magnets is due to Mr. F. W. Very, of this observatory.

[2] Professor Wright has had the goodness to platinize these delicate mirrors for us himself.

The glass plate which encloses the front of the galvanometer has optically plane and parallel sides, and the screen, placed at one meter distance from the mirror, is a portion of a cylinder one meter in radius, divided into 500 divisions of 1 mm. each. The optical arrangements for illuminating and forming an image of the wire form one of such precision that a motion of $\frac{1}{10}$ of one of these divisions can be distinctly noted. There is an independent provision, by means of which the image of a second opaque and inverted scale can be viewed by the observer through a telescope, not as in the ordinary construction, directed on to a flat, attached to the needles, but in which the concave mirror, already described, becomes itself the mirror of a Herschelian telescope. Ordinarily the condition of astaticism of the needle is such that without any damping magnet, it will execute a single vibration in not less than 15 or more than 30 seconds. Much greater sensitiveness can be given to it, of course, but without, as we have found, corresponding advantage.

For the purpose of forming an estimate of the sensitiveness of the instrument, it may be stated, that when making a single vibration in 20 seconds a deflection of 1 mm. division of the scale is given by a current of 0.000,000,000,5 amperes through the coils of 20 ohms resistance; and, as we have just remarked, a tenth of one of these divisions can be discriminated. That this degree of sensitiveness is associated with a real, and not nominal, corresponding degree of accuracy, is shown by the fact that many series of accordant measurements have been made when the maximum deflection did not exceed three such divisions; and that similar measures have been made in the invisible spectrum given by ice melting in a dark room, when the maximum deflection observed was 1.6 mm. and most deflections less than one millimeter. On the other hand, the exposure of the same bolometer to ordinary direct sunlight with only $\frac{1}{1000}$ of the current passing, *i. e.*, with the galvanometer shunted 1,000 times, would drive the needle immediately, and with violence, off the scale.

Our experience has shown us that this galvanometer, in conjunction with such a bolometer as we have described, is capable of recording a disturbance of rather less than $\frac{1}{10000000000}$ part. To attain corresponding accuracy in gravity determinations we should need to have a balance capable of weighing a kilogram which would give at the same time an unequivocal deflection for a difference of one one-thousandth of a milligram in either pan. A deflection of 1 mm. corresponds, in the case of such a bolometer as we have used in the lunar spectrum, or in that of melting ice, to a change of temperature in the bolometer strips considerably less than $\frac{1}{100000}$ of a degree Centigrade, and we have just seen that about $\frac{1}{10}$ of this can be shown. In other words, about one-millionth of a degree can be indicated by it, and a quantity less than one hundred thousandth of a degree not only indicated but measured. It will be obvious to the practiced observer, that this degree of accuracy will not be in reality reached, unless the bolometer strips are perfectly protected from all extraneous radiations and air currents, and especially unless the image is fixed upon the scale when the bolometer is not exposed to heat. This degree of precision we believe ourselves to have actually obtained.

ON THE ELECTRIFICATION OF A STEAM JET.[1]

BY MR. SHELFORD BIDWELL, F. R. S.

THE author showed that the capacity of steam issuing from a nozzle is greatly increased by bringing electrified points near it, and that its color is changed to orange-brown. Electrified balls and discs when placed in the steam produce similar effects, and when these are connected with an influence machine at work, the decoloration of the jet rapidly responds to each spark. On examining the absorption spectrum of the unelectrified jet, little or no selective absorption was detected, but on electrification the violet disappeared, the blue and green were diminished, and the orange and red remained unchanged. From these results the author concludes that electrification causes an increase in the size of the water particles in the steam, from something small, compared to the wave length of light, to about $\frac{1}{50000}$ of an inch in diameter. Allied phenomena with water jets have been observed by Lord Rayleigh, who found that a straggling water jet is rendered much more coherent by bringing a rubbed stick of sealing wax near it. These observations are of considerable meteorological interest, for the steam jet phenomena go far towards explaining the cause of the intense darkness of thunder clouds, and of the lurid yellow light with which that darkness is frequently tempered. After making his experiments, the author learnt that similar observations had recently been made by the late Robert Helmholtz, who viewed the steam jets by reflected light against a dark background. On electrification the jets became much better defined, and presented diffraction colors. Luminous flames also produced similar effects, and Mr. Bidwell has found that glowing touch-paper is equally efficient. Helmholtz conjectures that the sudden condensation may be due to molecular tremors or shocks imparted by the electrification upsetting the unstable equilibrium of the supersaturated vapor, just as a supersaturated saline solution is suddenly crystallized when disturbed. Another hypothesis suggests that condensation is caused by the introduction of solid matter into the jet by the exciting cause, thus providing nuclei upon which the vapor may condense. On reading Helmholtz's paper, the author tried the effect of gas flames on water jets, and found that when luminous they influenced the jet considerably, whereas non-luminous flames had no appreciable effect. He also found that luminous flames are positively electrified, and demonstrated this before the meeting.

Professor Rücker, in discussing the paper, said that he thought the surface tension of the films surrounding the water jets would be modified by the presence of an electrified body, and that the smoke from the touch-paper used in some of the experiments on steam jets would introduce solid particles and facilitate condensation. Mr. Richardson inquired whether a red-hot iron had any effect. Dr. Fison said he had made experiments on the electrification of flame, and found that potentials varying from + 2 volts to — 1½ volts could be obtained in the region within and surrounding a Bunsen flame. Professor S. P. Thompson commented on the contrast between Mr. Bidwell's experiments and those of Dr. Lodge on the dissipation of fogs by electricity, and also asked whether the color of the jet depended on the length of spark produced by the machine. Professor Forbes thought a crucial test between the two hypotheses of Helmholtz could be obtained by trying the experiment in a germless globe. The president, Professor Reinold, said he had recently noticed that gas flames were electrified. Mr. Bidwell, in reply, said he ought to have mentioned that the effect of flames on jets may be due to dirt, for if soap or milk be added to the water in the steam generator no effect is produced by electrification or flame. As to change of color with spark length, little, if any, variation is caused thereby. He had not tried whether a red-hot iron produced any effect on a steam jet.

ELECTRIC TRAIN LIGHTING IN AMERICA AND EUROPE.

AMONG the numerous papers read before the International Railroad Congress, recently held at Paris, was a report on the use of electricity, written by E. Sartiaux, chief engineer to the telegraph department of the Northern Railroad of France, and L. Weissenbruch, engineer to the Belgian post and telegraph department.

This paper treats of the present applications of electricity to railroad service, under three divisions; *i.e.*, lighting trains, lighting stations and working brakes. This is an interesting paper from a European stand point, and has some points of interest to the railroad men of the United States particularly that portion referring to train lighting. The results of trials of electric lights on railroad trains in the United States are mentioned in the paper. Regarding the cost of electric lighting, compared with that of gas and oil in trains, the joint authors have come to the following conclusions :—

1. That the cost of electric lighting by accumulators alone, charged at fixed stations, varies in the United States from 5 centimes to 5.6 centimes with lamps of from 12 to 16 candles, and that in Europe the cost is from 1.9 to 3 centimes for lamps of from six to eight candles, per lamp-hour
2. From experience obtained in Europe it is possible to charge accumulators by a dynamo driven off the axle at a cost not exceeding 4 or 5 centimes per lamp-hour for 5-candle lamps.

---

[1] Abstract of communication read before the Physical Society, London, December 6, 1889.—From *Industries*.

3. That in the United States the cost of lighting varies between 3.5 and 5 centimes per lamp-hour for 16-candle lamps in installations comprising accumulators, dynamos, and an engine supplied with steam from the locomotive.

On the continent the cost of Pintsch gas per lamp-hour (five or six candles) is 3.764 centimes, and of colza oil, 5.635 centimes. It will be seen that for lights of the same candle-power, gas would therefore cost about 11.8 centimes per lamp-hour, and oil about 16.9, as against 5.6 for electric lights; but really these deductions are based upon too few experiments to render the comparisons reliable.

The authors further say:—"It is impossible to consider the present condition of electric train lighting without being struck with the very considerable progress that has been made in the last few years; electricity comes very near meeting the requirements of the case, both as to the cost of maintenance and as to the beauty and intensity of the light. The almost entire absence of heat, the steadiness of the light, and the facility with which it can be placed at any desired point of a car or compartment, certainly make it preferable to any other mode of lighting, if it is desired to be able to read a long time without fatigue.

"The arrangement which appears to be most advantageous, is to place accumulators under or on each car, a single group for all the lamps, or a separate battery for *each lamp*, these accumulators being charged at fixed points, either with or without removal from the train. The weight of the accumulators necessary for 22 lamps in a car is about 1,100 pounds. (This is no more than that of the Pintsch gas apparatus, which varies from about 1,000 to 1,300 pounds per car, as stated by Mr. P. Lefavre in a report on the dead weight of trains.)

"Where for particular reasons, it is necessary to dispense with this additional weight, it is still possible to light successfully trains which are not to be broken up, by a dynamo placed in the baggage car and operated from an axle or by steam from the locomotive. When this latter plan can be combined with the heating of the train by steam, it seems to be a very economical method. The experiments in the electric lighting of trains are, however, so recent, that notwithstanding the importance of the results obtained, none of them are conclusive." The authors finish their report by recommending to the different railroads further experiments in this direction.

In our own country progress has been made principally in the direction of lighting by a dynamo and engine in the baggage car, supplemented by accumulators under each car, which are kept charged by the dynamo running in the day time as long as may be necessary. This arrangement seems to give the most satisfactory results, though it has yet been applied only to a few luxurious trains which are never broken up, and which run for long distances. It remains to be seen whether it can be made practically successful on trains of the usual character. Thus far it has been found necessary for a competent electrician to accompany each train, the apparatus requiring too much care to be put in charge of any of the trainmen in addition to their other duties.

The Intercolonial Railway of Canada has, however, continued experiments with accumulators alone, they being charged at three different points on its line, and running about 500 miles with one charge, when they are replaced by a fresh set. The number of 16-candle-power lamps in each car varies from 11 to 22, and more than 40 cars have been fitted with electric lighting. In the number of cars lighted, this road is equaled or exceeded by but one or two in America. The results obtained, are, on the whole, favorable, but the electric light is not exclusively depended on, the oil lamps having been retained in all these cars, and it may be said, frequently used. A fourth charging station is now being built, to save the necessity of sometimes extinguishing the electric lights on the return trip, owing to the charge in the accumulators having become exhausted.

The Boston & Albany Railroad has lately discontinued the use of electric lights on the limited express trains between Boston and New York, and substituted Pintsch gas. This step was taken partly because of the great expense attending the use of electricity (the accumulators being charged by electric lighting companies at either end of the line), and partly because of a considerable number of cases where the lights failed altogether or were unsatisfactory. It was precipitated by the suspension of electric service in New York city, rendering the use of the oil lamps necessary on one trip each day in one direction in such of the cars as were supplied with them.

The drawing-room cars were fitted only with electric lamps; hence these were in darkness, and after the second day were withdrawn from service, until they could be fitted with gas lamps.

Attempts were made, it will be remembered, for a few months in 1887, on the Connecticut River Railroad, to run a dynamo from one of the axles of a baggage car, but after successive trials of transmissions by belts, ropes and chains, it was abandoned as impracticable, and there have since been no experiments of this kind on this side of the Atlantic. The reason of its success abroad lies in the fact that the cars there have but a single pair of wheels at each end, and because of the few curves and high speed of trains on the principal lines. In all these installations, the direct source of supply for the lamps is a battery of accumulators, located either in the baggage car or distributed through the whole train. The function of the dynamo is to keep these fully charged. An automatic switch is also necessary to cut off the connection between the dynamo and accumulators whenever the speed falls below a certain limit, else the accumulators would discharge themselves through the dynamo and possibly ruin it, besides greatly injuring themselves. Skilled attendance is also advisable, and in many cases absolutely necessary.

Electric lighting of cars in America, must, therefore, be considered at present a luxury, to be used on a few trains in exceptional circumstances, and not yet developed either in appliances or in cost, to a point where it can compete with oil or gas for every-day use. But as the luxuries of one generation become the necessities of the next, the beauty, comfort and healthfulness of the electric light may yet make it indispensable to all first-class railroads, and inventive genius will yet produce apparatus for generating it, which is convenient, reliable, and cheap.

The Swiss Railway Union, at a meeting on Nov. 2 last, passed the following resolution: "That, considering the actual position of electric lighting, it is not desirable to extend the lighting of trains by gas, but that it is preferable to continue the investigation of the electric lighting problem, and to extend experiment." Experience in this country will hardly warrant so strong a statement, but further investigation is certainly needed before a final determination.—*Railroad Gazette.*

RAILROAD SIGNALS AND SIGNALING.[1]

At the meeting of the New England Railroad Club at Boston, December 11, Mr. R. H. Soule, of the Union Switch & Signal Co., delivered an interesting address on the above subject, from which we make extracts below.

Beginning with a brief historical sketch of the art in this country, with allusion to the important features inherited from English practice, Mr. Soule continued:—

The semaphore has been referred to as the best form of visible signal. This is certainly true for all signals that are approached at high speed, and must be seen from a distance. Custom has prescribed that home signals should be painted red and distant signals green, although at least one large system in the west has adopted yellow as the standard color for all semaphores; the claim being that the semaphore is merely a position signal, and that therefore it may be of that color which will be most effective, and will make it visible from the greatest distance under adverse conditions. It may be confidently stated that when other forms than the semaphore are used as high-speed signals, the reason lies either in the desire to use a cheaper signal, or in the fact that the motive power used to work the signal is not sufficient to overcome the inertia of the semaphore in starting or to resist its momentum in stopping. It is for this latter reason, probably, that the semaphore is not used where the propelling force is a weight, which is made active through the instrumentality of an electric current and an electro-magnet. This applies principally to high-speed signals; for low-speed signals to govern shifting operations, or what are known as reverse movements, it has hitherto been customary to use a low down disc signal, commonly termed a pot signal; but more recently there is a marked tendency towards the use of dwarf semaphores for this purpose. The almost universal custom in this country is to hang the semaphore blade so that it will point to the right when viewed from an approaching train which it governs. The Boston & Albany is the most notable exception. Some effort has been made to secure the successful introduction and use of position signals by night. The Boston & Albany accomplishes this by the expedient of equipping each semaphore signal with three lights, so connected that when the blade is in the horizontal, or danger position, two lights, in the same horizontal line, are displayed, while with the blade hanging down, in the clear position, two lights, in the same vertical line, are displayed. More recently, on other roads, illuminated semaphores have been devised and introduced.

Referring to compensators and the difficulties incident to their use, the speaker said:—

In general they were expensive, and sometimes dangerous, as when a certain one of the two wires broke, in which case the signal might be left in the clear position; it subsequently developed that with two wire connections it was entirely practicable to omit all automatic compensating devices, and such is now the very general practice. Both wires are fitted with adjusting screws, which need to be used only between extremes of temperature; ordinary slight variations of temperature result in no movement of the signal blade, as both wires are affected equally; neither are the wires thus subjected to any undue strains; in their natural condition they are full of kinks, which give and take enough to more than accommodate the alteration of length due to changes of temperature such as occur in practice.

The principal of preliminary interlocking was formulated as

---

1. From the *Railroad Gazette*, December 13, 1889.

follows: "A lever which is to lock certain levers and release certain other levers must complete all its locking functions before the beginning of its stroke, and must not accomplish its releasing or unlocking functions until after its stroke is completed." Mr. Soule continued: the spring catch affords the means by which it is possible to meet these conditions, and it is now invariably used to actuate the interlocking mechanism; this is common to all successful machines, although the means by which it is accomplished may differ. The following original rules for interlocking were formulated in 1876, and are believed to be sufficient for present guidance.

I. Each home-signal lever, in that position which corresponds to clear signal, must lock the operating levers of all switches and switch-locks which, by being moved during the passage of a train running according to that signal, might either throw it from the track or divert it from its intended course, or allow another train (moving in either direction) to come into collision with it.

II. Each lever so locked must, in one of its two positions, lock the original home-signal lever in its danger position; that position of lever being taken which gives a position of switch, or switch-lock, contradictory to the route implied by the home-signal, when clear.

III. Each home-signal lever should be so interlocked with the lever of its distant signal that it will be impossible to clear the distant signal until the home-signal is cleared.

IV. Switch and lock levers should be so interlocked that crossings of continuous tracks cannot occur, where such crossings are dependent upon the mutual position of switches.

V. Switch levers and their lock levers should be so interlocked that the lever operating a switch cannot be moved while that switch is locked.

When these rules are followed in practice their mutual bearing, one on another, becomes evident, and it is found to be unnecessary to locate a separate locking dog for each locking process referred to. The practical process of making an interlocking chart becomes an instinctive matter with those who are habitually engaged in that class of work.

Even the excellent Saxby & Farmer machine has some features which are susceptible of improvement. The Union Switch & Signal Co. have been required to carry 560 different patterns of locking dogs to meet all the cases of exceptional and special locking which have occurred in their practice. By the recent introduction of what is known as tongue-locking, which may be used as an auxiliary to the Saxby & Farmer system, the number of such patterns have been reduced from 560 to 20. The advantage thus gained is being still further pursued, and the company is about ready to introduce a new interlocking machine, from which the old Saxby & Farmer flops and locking dogs have been eliminated. The new interlocking mechanism revives the use of bars with beveled faces, as in the Stevens system, but under such radically different conditions that the rapid wear which characterized the Stevens locking, and seriously impaired its efficiency, cannot occur. The working parts of the interlocking mechanism of the new machine are all of wrought iron, steel or malleable iron, and their durability thus assured.

The tendency of recent practice is toward still greater concentration than had been effected by the mere assembling of switch and signal levers; this applies to the track work as well as the machine and connections. A terminus which has been planned with reference to its control from an interlocking station will, in general, be found equipped with lead tracks of high frog angle and with double slip switches. * * * * Originally separate levers were used for each switch, lock and signal; at the present time it is common practice to work the two switches of a crossover with one lever; if movable frogs are used they may be moved by the same lever; it is now usual to move a switch, its lock and its detector bar by a single lever; as the lock bolt must be withdrawn and detector bar reversed before the switch is shifted, and as both must be restored to normal position again after movement of switch is completed, special and ingenious mechanism has to be employed to accomplish this result from the single stroke of a single lever. A home and a distant signal are often worked by a single lever, a special device being introduced into the connections, which insures the clearing of the home signal before the distant signal is cleared. By holding the lever at midstroke the home signal may be held at clear and the distant signal held at caution. In working signals the introduction of selectors has contributed toward greatly reducing the number of levers required for the operation of an interlocking plant. The principle of the selector is this:—Given a group of signals, only one of which can show clear at a time, then only one lever in the interlocking apparatus need be provided for the operation of those signals; the line of connections from the working lever is led out to some convenient point in the direction of the signals and there terminates in the selector; from the selector run independent lines of connection to the several signals; the function of the selector is to engage the lever connection with one or another of the signal connections, and this is automatically accomplished by the connections to the several switches involved, alongside of which switch connections the selector must be located. The result is, that, when the lever is pulled, that signal is cleared which corresponds to the setting of the switches; in fact, the selector is an auxiliary interlocking apparatus; its application to the connections of a group of signals reduces the number of levers to be handled in the interlocking station, but, in connection with what are known as indicators, the selector may be utilized to reduce the number of signals themselves. An indicator is a device by which one of several diverging routes implied by a signal is designated and defined; indicators generally consist of a set of discs located just below the signal blade and numbered to correspond to the several routes. When the signal is at danger, the indicator discs are concealed behind a screen; when the signal is cleared that disc which designates the route prepared by the switches is elevated into view and brought into range with a lamp placed immediately behind, so that the number on the disc may be observed either by day or night.

The utilization of these several expedients, such as the switch and lock movement, the home and distant signal movement, the selector and the indicator, have made it possible to effect a large reduction in the cost of interlocking plants. Two instances from recent practice will illustrate this. The interlocking apparatus at the Grand Central Station in New York city, as rearranged in 1887, comprised 116 levers. Within two years the change in terminal arrangements and the increase in volume of traffic necessitated a rearrangement of the yard tracks, and the opportunity was taken advantage of to utilize the more modern interlocking appliances and connections. The railroad company decided to introduce 11 additional switches, each of which was to be equipped with a lock, also 29 locks on switches not previously equipped, and 12 additional signals. Had a separate lever been required as formerly for each switch, each lock and each signal, the number of levers would have been increased from 116 to 179, but, on the contrary, the new plant recently put in operation, has but 87 levers, a relative reduction of about 51 per cent.

A still more striking illustration may be had by comparing our present practice, not with our previous practice, but with the English practice of to-day. The Union Switch & Signal Co. recently submitted to Saxby & Farmer a plan of the new terminus of the Central of New Jersey at Jersey City, together with a specification of the signaling required, and a request that they should state the number of levers that they considered necessary to properly operate and interlock the terminus in question. They replied that they would recommend the use of an interlocking frame of 185 levers; but the plant actually established in Jersey City [see *Railroad Gazette*, June 28, 1889] consists of but 66 levers, a relative reduction of about 64 per cent., and yet it accomplishes all that the English plant of 185 levers could accomplish.

If the English and American practice in the case of the Jersey City plant are a fair criterion, then the great London Bridge apparatus, the largest in the world, if rebuilt upon American principles to-day, would be reduced from 280 levers to 100. Over-conservative public opinion has apparently influenced the Board of Trade to place legal restrictions on manufacturers and railways, which debar them from enjoying the benefits and economies of concentration.

Mr. Soule then described electro-pneumatic interlocking apparatus, referring to the first one ever made—that at Philadelphia in 1876. The fluid now used by the Union Switch & Signal Co. in the winter is a mixture of one part chlorate of calcium to three parts of water,

Thirteen of these pneumatic interlocking machines have been put in service during the last five years, and the machine now being put in at Kansas City has 36 levers for the operation of 59 switches, with locks and detector bars, 57 signals, 87 indicators and one set of movable frog. At Pittsburgh, on the Pennsylvania, there may be seen four plants in operation—at Fourteenth street, Seventeenth street, East Liberty and Wilkinsburg. The same supply of compressed air feeds the four pneumatic interlocking plants and the twelve sets of pneumatic block signals.

Having previously described automatic clock-work block signals, Mr. Soule went on to give a brief résumé of block signaling, including the Sykes system, and followed this by an account of the automatic pneumatic block system at Pittsburgh, described in the *Railroad Gazette* of August 23 and September 6 last. The Union Switch & Signal Co. are now introducing this system on seven miles of the Central of New Jersey, between Jersey City and Bergen Point. The road has four tracks for a portion of this distance, and double track the rest; the seven miles will be subdivided into 19 blocks, which will therefore average three-eighths of a mile in length.

In conclusion, Mr. Soule said:—From the facts presented it appears that recent practice in signaling and interlocking has resulted in substantial economies, which have been secured principally by concentration. It would seem difficult to accomplish much more in that direction with manual apparatus, and the outlook for further gain is probably in the extended use of the pneumatic system, which is very efficient either for interlocking junctions and terminals, or for the operation of a system of block signals; the pneumatic method possessing distinct and decided advantages for lines which have a heavy traffic.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Resumption of Traffic by the Storage Battery Cars on Fourth Avenue.—The Fulton Street Electric Railway.—Danger from Low Tension Currents.—The New York Electrical Society.—The Commercial Telegram Company's Main Office in the Sheriff's Hands.—The Mc.Dougal-Martin Electric Company.—Rumored Preparations of the Bell Telephone Company to Fight for the Telegraph Business.—Wholesale Destruction of Electric Light Lines by the Department of Public Works.—Removal of J. H. Bunnell & Co.

THE resumption of traffic by the storage battery cars on Fourth avenue was an agreeable surprise to those who have been watching the gradual supersedure of horses, upon the only line in the city where electricity has gained a foothold. The number in operation will be gradually increased as the cells are prepared, under the process permitted in the decision of Judge Lacombe.

It is reported that the franchise of the Fulton street electric railway is offered for sale, but there are no purchasers. The reason for this lack of interest is supposed to be the fact, that under the terms of the charter 35 per cent of the gross receipts were to be turned over to the city treasury. The rails and electric conduit remain in position but have never been utilized.

In Mr. Edison's recent article in the *North American Review*, the admission was made that low tension currents might cause intense heat, even if they did not destroy life. It is well known that this danger has been carefully guarded against by the careful construction of the Edison system. This caution has not however been exercised by other companies, and the daily newspapers have suddenly discovered, and are making the most of the fact, that currents of low voltage may cause fire. Owing to the sensitive condition of the public's mind, it appears probable that there may be an outcry against electric wires of all descriptions, which will be generally detrimental to electrical industry.

The meeting of the New York Electrical Society, December 11th, proved to be the most interesting and best attended of the season. Mr. S. Dana Greene addressed the meeting, on the "Development of Street Car Traction." He was followed by Mr. Frank J. Sprague, who believed the electric railway had nothing to fear from the introduction of the cable system.

The main office of the Commercial Telegram Co., at 18 Broadway, has been taken charge of by the sheriff, who levied upon the property to satisfy two judgments, one in favor of J. W. Mackay for $287,312, and the other for $32,120 in favor of E. C. Platt. It is said that the company's plant will be sold within a short time.

Up to this writing, the State Electrical Executioner has made no report to the daily *World* of the amount of his receipts in ten-cent subscriptions, which were to be devoted to legal services in behalf of the public against the electric lighting companies.

The McDougal-Martin Electric Co., recently organized, will devote its attention principally to motor work. Mr. McDougal was formerly superintendent of the Daft factory at Marion. Mr. C. W. Price, who is interested in the company, was also with the Daft company at the New York office, 115 Broadway.

The New York *World* has devoted a column each day for about a week to showing how the American Bell Telephone Co., through the American Telephone and Telegraph Co., was gradually building up opposition lines, which, upon the expiration of its contract with the Western Union Telegraph Co., would be used to crush the latter. For this reason, it is claimed that Jay Gould is anxious to sell out to the government. The whole makes a very plausible story, but it is very pertinently stated that there is nothing to prevent the telegraph company from engaging in the telephone business also, so it seems very probable that both companies will see the wisdom of continuing their amicable relations.

The setting aside of Judge Andrews's injunction against the city authorities preventing their interference with the wires of the electric light companies, was the signal for a general onslaught upon existing lines that has been of incalculable damage to vested interests. By the stopping of dynamos and proper procedure the work could have been done in a much more effective, if less sensational manner. As it is, about $100,000 worth of new wire has been practically ruined, and the business of the companies virtually suspended. Even the newspapers appear to be tired of the theme, and the era of darkness is teaching them to look fondly upon the gas interests, which for years have given them material for paragraphs, when the mother-in-law and ice cream had become wearisome.

The well-known electrical supply house of J. H. Bunnell & Co. has moved into an apparently desirable location at the corner of Cortlandt and Washington streets. This was formerly out of the electrical trades district; but many engineering companies are now in that vicinity, while its proximity to the Pennsylvania Railroad station makes it particularly accessible for out-of-town visitors.

NEW YORK, December 27, 1889.

PHILADELPHIA.

Brick Machinery Run by Sprague Motors at the Master Builders' Exchange.—Ordinances Touching Telegraph and Electric Light Wires.—A New Letter-Stamping Machine.—Poor Gas Light in Philadelphia Giving Way to Electricity.—A Large Business House Will Use Electric Light Throughout.—Mr. Ralph W. Pope's Lecture at the Franklin Institute.—The Electric Power Co. of Philadelphia, Chartered.—Williamsport's Electric Light Plant Now in Operation.

AT the Master Builders' Exchange, Nos. 18–24 S. 7th street, this city, there is a very interesting exhibit made by the Chambers Bros. Co., brick machinery manufacturers, of this city. By courtesy of the exhibition department of the exchange they were offered space in which to exhibit during the Brickmakers' Convention here a working model of the well-known "Chambers" brick machine, and joining forces with the Sprague electric motor people, have their machine making daily large numbers of miniature bricks by electric power.

The electrical committee of councils received from a sub-committee of its members a few days ago, a favorable report on the ordinance giving the Western Union Telegraph Co. permission to lay its wires in the conduits of the Bell Telephone Co. Councilman E. W. Patton declared that the bill was faulty, and opposed it. After some discussion it was decided to report the ordinance favorably to councils.

Negative reports were ordered upon an ordinance giving the Southwestern Electric Light Co. permission to erect poles and string wires.

A new letter-stamping machine has been put on trial in the Philadelphia post-office. It is run by electricity, will cancel about 25,000 letters an hour, and has a register that keeps count of each letter stamped. This may do away with the services of a few stampers.

"Why has the Bureau of Gas been compelled to resort to electric lights?" was asked of Director Wagner. "Ask the farmer why he sends his best produce to market and consumes the inferior stuff in his household," was the general's reply. But the general is "away off" in this matter. For some time past the gas in this city has been of the worst imaginable kind, and numerous storekeepers who use large quantities of gas in their business, threaten to substitute electricity if the quality is not improved. This is about what it will come to, eventually any how.

Owing to the increase of their retail business, Sharpless Brothers have decided to remove their wholesale department from 8th and Chestnut streets to the large building formerly occupied by Young, Smyth, Field & Co., at Nos. 812 and 814 Market street, and the entire structure, five stories high and 40 by 281 feet, will be lighted throughout with electricity.

Mr. Ralph W. Pope, of New York, secretary of the American Institute of Electrical Engineers, delivered a lecture at the Franklin Institute in this city on the evening of December 16, on "Electricity—Its Past, Present and Future." The lecture room was crowded with an attentive and appreciative audience. Mr. Pope handled his subject in a masterly manner, and was frequently interrupted by applause during the hour and a half which he occupied in its delivery. At its close, Mr. Pope was heartily congratulated, and quite a number of people detained him on the platform, plying him with questions upon points in his lecture. These inquisitive people were quickly satisfied and left the room with an enlightened and broader view as to the uses and power of electricity.

A charter has been granted at Harrisburg, to the Electric Power Co. of Philadelphia, capital, $150,000.

Williamsport's new electric light plant is now in full operation.

PHILADELPHIA, December 18, 1889.

BOSTON.

The Great Fires at Lynn and Boston; Newspaper Investigations and Official Investigations; Private and Official Opinions and Recommendations.—Electrical Displays at the Maritime Exhibition.—Electrical Trade Notes.

THE two great fires in our vicinity recently, that at Lynn November 26, and at Boston November 28, with the electrical questions which have been raised, since then, have been absorbing topics among citizens and especially those interested in electrical matters.

The fire at Lynn, was caused by the heat of a kerosene lamp in the vicinity of oily leather in an inflammable structure. A meeting of the citizens with the mayor and aldermen was held on December 1. As the result of the meeting, a petition, which includes the following, will be circulated for signatures :—

> That the city council shall prohibit, in this fire district any telephone wires or any electric light wires unless the same are placed underground; that the telephone central office be removed to a location outside of this fire district, thereby taking a thousand wires out of Central square and the streets in its immediate vicinity; and that the city council locate a special street to run the telephone poles and wires upon on the northern side of Buffum and Cambridge streets, and south of Market street, across Pleasant street.

Concerning the big Boston fire of Thanksgiving Day, the daily press, as usual, are extremely busy investigating the cause. At first it was quickly settled by them, that the falling of an electric time wire across the trolley wire of the West End Street Ry. Co. was the immediate cause of the disaster; but that hypothesis was quickly set aside when Mr. Pearson, the electrician of the road, informed the investigators, that there had been no current in the portion of the trolley wire when the cross was found. The cause was then explained by the crossing of the time wire with an electric light wire, which seems probable, though not proven. It appears that the clocks on the time circuit from the alleged cross to the seat of the fire were found to have been either burned out or stopped just before the fire was discovered; and as the Brown, Durell & Co. building contained the central station of the American Electric Time Co., this building being the starting place of the fire, color is given to the charge that electricity was the cause of the destruction of $5,000,000 worth of property.

The fire commissioners are still investigating the circumstances, about 150 pages of evidence having already been taken, and there will probably be as much more, taking up perhaps another month.

A conference held on the evening of December 1, at Mayor Hart's house, was attended by Professor Thomson of the Thomson-Houston Electric Co., Joseph W. Larish of the Western Union Telegraph Co, Captain Griffin and President Whitney of the West End Street Railway, Mr. Denver of the New England Telephone Co., President Gilbert and ex-Mayor O'Brien of the Boston Electric Light Co., Captain Flanders of the city's fire alarm department, and Corporation Counsel Richardson. The conference agreed that the increase in electric wires is a constant source of danger, as the highly charged wires are constantly liable to come in contact with ordinary telegraph and telephone wires and thus to carry destruction into any building that has a telephone or is otherwise connected with a network of wires that covers the city. It was agreed that an effectual control of all these wires by a competent officer is imperatively needed, being alike in the interest of the companies and the public. It was agreed also that the city can control all wires by a properly drawn ordinance. Some of the gentlemen expressed great faith in the safety fuse used by many electric companies.

Mayor Hart in addressing the board of aldermen, used the following words:—

"The Bedford street fire of November 28, which destroyed precious lives and millions in property, is suspected to be the direct result of a low-power wire coming in contact with a highly charged wire. Should this suspicion prove unfounded, the fact still remains that ordinary telephone and telegraph wires are an immediate source of danger the moment they touch an electric light or power wire, such as may be found in all parts of the city and are daily increasing. This crossing of wires is the greatest danger with which we have to contend. Putting the wires underground is apt to increase the danger, because it brings all sorts of wires into close proximity. The true remedy is known to electricians and fire insurance companies, and consists in a safety fuse of fusible alloy, inserted in every telephone or any other electric wire just before it enters a building. The cost of this contrivance is trivial, and the protection it affords is almost absolute, in that it breaks the continuity of conductors when these become heated to the danger point. A great, constant and increasing danger can thus be averted provided your honorable body will pass an ordinance with a penalty attached, for every case of disobedience, requiring every telephone, telegraph and other electric wire, that enters any building in Boston, to be provided with a safety fuse or fusible alloy, satisfactory to the fire commissioners or to the superintendent of the fire alarm."

In closing, the mayor said:—

"I renew my recommendations of October 21, and I may add that, while our city has full power to protect itself and the people of Boston from all danger occasioned by electric wires, this power has not been exercised by adequate ordinances and through a qualified officer."

This plea for the protection of the city and its inhabitants was followed by a few words from the fire commissioners, before the same body. After asking for an appropriation large enough to replace the apparatus lost by the falling of buildings, the commissioners said:—

"With the bare trolley wire threading our narrow streets, there will be a constant and all-pervading menace of a repetition of such conflagrations as that through which we have just passed, and the city will be fortunate if the fires caused thereby are confined to one building or one section at a time. Moreover the overhead feed wire cable stretched over poles in some streets must form a source of delay and trouble in preventing the speedy use of ladders. The electrical question is one which affects the fire department more than any other public interest. If measures can be devised to lessen these dangers to life and property, it will confer a great benefit upon this department, and, the commissioners believe, upon the public generally."

The fire has more or less hastened the stringing of guard wires over the trolley wire of the West End Road. As a measure of protection this is rather effective, there being three guard wires running above and parallel to the trolley wire, thus keeping flying wires from making a contact with the same.

An excellent opportunity to examine electrical machinery and the applications of electricity to lighting and power uses, is offered at the Maritime Exhibition, now being held here. The installations are numerous, and reflect credit upon the exhibitors. Walking down the main aisle the sight is everywhere impressed by the electric lights, arc and incandescent, in great profusion. Nearing the centre of the hall one hears the rumble of cogs, and glancing in that direction he sees the Thomson-Houston Electric Co.'s exhibit, surrounded by a halo of many colored incandescent lamps. This exhibit consists of their electric hoisting machine or "donkey." It is designed to work on an incandescent circuit, and has a capacity of 10 h. p. It will lift a half-ton tub of coal or 1,200 pounds at a speed of about 200 feet per minute. The machine is handled entirely by three levers and is under perfect control by the operator. It is fitted with all the latest devices for motor work, carbon brushes, laminated gear wheels, self-oiling bearings, etc. The complete installation of this company, comprises 10 machines, a 10,000 c. p. search light and 350 incandescent lamps.

A 400-light incandescent dynamo is run by an Armington and Sims engine and link leather belting. The search light is similar to those in use upon the naval vessels, it is run by a dynamo in the basement which receives its power from a Westinghouse automatic engine by means of the Evans friction cone. This system is invaluable aboard ship, where room is so valuable since it dispenses with belting altogether. Two 15 h. p. generators driven by the main engine furnish power for the various motors in use about the building. About 25 h. p. in a number of T-H. motors run silk looms, printing press, pump, fan blowers, etc. The Lamson Store Service Co. have a variety of cash railways run by a ½-h. p. Eddy motor, and Cabot and Holtzer have a 5 h. p, Eddy motor on exhibition, besides an interesting exhibit of primary and secondary batteries, and other electrical furnishings. The "C. & C." Electric Motor Co. have a number of small motors running various machines, lathes, etc.

The annual meeting of the Boston Electric Club, was held on Thursday evening, December 12, in the club room No. 7 Park street. The business transacted was the election of officers for 1890; the balloting resulted as follows:—President, Henry B. Cram; first vice-president, A. L. Rohrer; second vice-president, Geo. B. Neal; third vice-president, G. W. Adams; fourth vice-president, C. W. Holtzer; secretary, R. F. Ross; treasurer, F. J. Boynton; historian, G. W. Mansfield. A board of 20 directors was also elected, the president and four vice-presidents being added by a vote. It was voted to hold the banquet on January 6, 1890, at which time the officers will be installed and the reports of the year read.

The Edison Electric Illuminating Co. have issued a small catalogue of electric power users, employing their current as a motive power. An examination of its pages discloses the fact that there are 226 firms in this city, representing 32 industries, using electricity from the Edison circuits for power purposes. This company has also published a card setting forth the prices at which they will furnish power to consumers. This is undoubtedly an excellent idea, for the public know but very little about the cost of electric power. As stated in their handbook "the electric motor is the safest, quietest, cleanest, simplest, most reliable, handiest and most economical prime mover in existence. The Edison company here have recently started, or have about ready to start, 1,300 lights in Boston; two 500-light dynamos in Marlboro, Mass.; 900 lights at Manchester, N. H.; 900 lights in Augusta, Me. Total, 4,100 lights.

The eastern office of "C. & C." Electric Motor Co. have within the last few months installed the following:—18 ⅛-h. p. motors, 6 ¼-h. p. motors, 4 ½-h. p. motors, 2 1-h. p. motors, 4 2-h. p. motors, 2 3-h. p. motors, 2 4-h. p. motors, 2 10-h. p. motors, 90 fan outfits; an aggregate of 40 power motors and 90 fan outfits.

The Standard Electric Co., of Vermont, have the following installations:—

Boston, Hyde Park, E. Walpole, Orange, Newburyport, Spencer and Beverly; in Massachusetts, 2,450 lights; Whitefield and Milton, N. H., 400 lights. Benton and Springvale, Me., 1,200 lights; Clinton, N. J., 500 lights; Lyndenville, Vt., 125 lights; Central Falls, R. I., 1,300 lights, a total of 5,975 lights.

The Mather Electric Co. have put in about 9,000 lamps in Fitchburg, Lowell, Nashua, Hartford and Boston. And still the good work goes on.

The Boston theatre is the fifth playhouse in the city to be fitted with electric lights. There will be no lack of appreciation of the change from gas, alike from those who have felt the discomfort of heat in the spaces under each gallery and from those who have sat in either of the upper galleries and have had to face the great chandelier.

BOSTON, December 18, 1889.

.... As Americans it does not behoove us to ask the authorities to pass laws which will limit our work to that particular system that we have partially developed.—*George Cutter.*

CHICAGO.

The Electric Club; Mr. F. G. Beach, the New President, Takes the Chair.—Reconsideration of the Resolutions on Mr. Edison's North American Review Article.—A Paper on Arc Lighting in Chicago by Mr. C. E. Gregory.—Resolutions on the Death of Mr. E. S. King.—Mayor Hart, of Boston, Examines Chicago's Electric Lighting Methods.—His Approval of its Underground Work.—A Chicago View of the Electric Light Situation in New York.—Electrical Subscriptions to Chicago's World's Fair Stock.—The Northwestern Association of the Massachusetts Institute of Technology Graduates.—Alleged Use of the Telephone by the Cronin Conspirators.—A Novel Use of Incandescent Lamps.—Work of the Electric Light Association Committee on the Copper Duty.—Success of Electric Lighting in the Auditorium.—"Drop a Dime in the Slot."—The New Offices of the Edison and the Sprague Companies.

AT the meeting of the Chicago Electric Club, December 2d, President Beach occupied the chair for the first time. In calling the meeting to order he thanked the club for selecting him as its presiding officer, and suggested that steps be taken for the formation of a club library. The resolutions adopted at a previous meeting, which expressed the members' disapproval of Mr. Edison's article on the "Dangers of Electric Lighting" in the *North American Review* were reconsidered. This action was taken at the suggestion of Mr. Sunny, who had drafted the resolutions. He said his opinion regarding Mr. Edison's article was unchanged, but he deemed it unwise for the club to take action on it, for the reason that it might involve the club in a controversy on a trade matter. He thought purely business affairs should not engage the attention of the club. He continued to believe, however, that Mr. Edison's article was unjust and incorrect. Mr. Sunny's views were accepted by the club and the vote for a reconsideration of the resolutions was unanimous. The treasurer, Mr. F. S. Terry, presented his report, showing that the club was in a flourishing financial condition.

At the meeting of December 16th, Charles E. Gregory, of the Sperry Electric Co., presented a paper, in which he traced the development of arc lighting in Chicago. There were at the present time, he said, about 6,000 arc lights in operation in Chicago. He predicted that in 1892 there would be at least 10,000 arc lights illuminating the city.

At this meeting the club adopted a series of resolutions in memory of E. S. King, of Jacksonville, Ill., an honorary member, who died recently.

Mayor Hart, of Boston, was in Chicago a short time ago, and devoted considerable time to the examination of the local electric light systems. He has been traveling about the country to post himself on electric lighting generally, but particularly to gain information which may aid him in dealing with overhead wires in Boston. He thought the overhead construction in Boston was extremely bad. A heavy storm, he said, would tangle the circuits in fearful confusion. It is a noticeable fact that on his return to Boston Mayor Hart said, in reply to the questions of an interviewer, that Chicago had done more real honest work in the way of putting wires underground than any city in the country. He thought that Chicago's system might serve as a model for Boston.

"I am not a believer in faulty electric light circuits," said a gentleman a few evenings ago to a party of friends who were discussing the recent fatalities from electric light wires in New York city, "but I'd run my chances rather than to have darkness in the city. Light at night is the friend and protector of an honest man, and one needs it badly in New York city. I don't think there is any need of bad circuits, but I am simply speaking of a choice between two evils, and we often have such alternatives to select from in this world, unfortunately. I have been impressed with the fact that the New York companies which have allowed their systems to become so dangerous have a great deal to answer for. They have hurt the business greatly throughout the country. Why, my wife wants me to get out of the business, she is so impressed with the dangers which the newspapers have pointed out. I am a believer in both the high and low tension systems. I am not prejudiced against direct or alternating currents, so I do not speak with the idea of depreciating any system. I want work well done and safely done; that is all. I find that persons want all sorts of guarantees made when a plant is installed, which were not thought of before these fatalities in New York. I would like to bring suit against the New York companies to obtain money enough to cover the sums I would have made had not people been too scared by the New York accidents to buy plants. When a man tells me that he is afraid to install a plant now, I, of course, tell him my system is perfectly safe, but he always says, 'Oh, pshaw! don't say that; don't try to fool me; all you electric light people say that.' The New York accidents constitute a mighty argument for good construction. I hope it will be heeded. It is no use talking to people about the deaths from steam cars, or gas, or boiler explosions, or cable cars, or elevators. There may be many more accidents than from electric light wires, but the fact doesn't remove the fear which people have begun to entertain for wires. People simply say you can guard against other dangers, but not against those from the wires."

B. E. Sunny, chairman of the committee appointed by Mayor Cregier to represent electrical interests on the Chicago World's Fair committee, has reported the following stock subscriptions with the accompanying two per cent. payment:—Western Electric Co., 250 shares, clerks, 98; F. W. Horne, 15; S. W. Trawick, 5; Brush Electric Co.'s employés, 55; Thomson-Houston Electric Co., 250, employés, 150; Chicago Arc Light and Power Co., 100, employés, 150; W. A. Kriedler, 10; F. DeLand, 10; Central Electric Co.'s employés, 122; Foree Bain and employés, 22; Electrical Supply Co., 25, employés, 15; Knapp Electrical Works, 25; T. P. Bailey, 15; C. & C. Motor Co., 15; Chicago Edison Co.'s employés, 96; Sperry Electric Co. employés, 53. In addition to these the workmen employed by the Western Electric Co. have subscribed for 300 shares, making a total of 1,781 subscribed by the electrical fraternity of Chicago.

The Northwestern Association, of the Massachusetts Institute of Technology, held its third annual meeting in Chicago, December 7th. Among the guests of the evening was Professor Charles R. Cross, who has charge of the department of electrical engineering in the institute. Louis A. Ferguson, of the Chicago Edison Co., read a paper on "Applications of Electricity."

In his summing up speech for the defense in the Cronin case, one of the attorneys thus spoke of the charge that two of the conspirators had been heard communicating by telephone:—"The telephone is a very useful invention, but I will venture to state without fear of successful refutation that that instrument was never yet made use of by criminals, because it is a public thing. Anybody can hear that has any sort of communication with the wire at either end, and more than all that, it is improbable and unnatural that men should employ the telphone for the purpose of communicating any secret."

The managers of the Westinghouse station at Englewood, which is now a district of Chicago, made a novel installation a few evenings ago. At a bazaar, several young ladies gave a drill in military dress. They wore helmets in which were placed red, white and blue incandescent lights. In certain parts of the drill the lamps were illuminated and the effect was very striking. The operation was very simple. A converter was placed on the outside of the building. The secondary wires ran under the stage and were connected to a number of brass plates on the floor. The young ladies were properly wired from the lamps on their helmets to the heels of their shoes, on which were fastened small brass plates. When they stood on two of the plates on the stage the circuit was complete and the lamps flashed up brilliantly.

C. A. Brown, chairman of the committee of the National Electric Light Association, which was appointed to memorialize Congress to remove the copper tariff, has prepared the petition and states that the committee is prepared for aggressive work. He says that the interest which has been shown in the object of the committee is highly encouraging.

The opera season is now in progress, and the magnificent auditorium is splendidly illuminated. The arrangement of lights was studied with great care and their decorative effect is almost as important and striking as their illuminating power. Many new electrical devices are used on the stage to add to scenic effect.

S. M. Dowst and Frank H. Hosmer have invented an ingenious little appliance for a telephone, the principle of which is that the insertion of a dime in a slot is a condition precedent to the use of the instrument.

The Edison and Sprague companies have moved into new offices in Chicago in the Rialto buildings. They are the finest offices occupied by electrical companies in the city. The floor space is 6,000 square feet, one-fourth of that on the main floor of the building.

CHICAGO, December 23, 1889.

ST. LOUIS.

The Consolidation of Lighting Interests in St. Louis.—The Municipal Electric Light and Power Co. and its City Contract.—A Temporary Electric Installation by the Laclede Gas Light Co.—The Westinghouse Station of the Missouri Electric Light and Power Co.; It Will be Ready for Service January 1st.—Official Investigation of the Electric Light Combination.—The Short Series Electric Railway.—The Thomson-Houston Railways.—The Fort Wayne Plant at East St. Louis.—Electric Railway Notes.—The Southwestern Electrical Engineering Co.

THE Municipal Light and Power Co. has passed into the control of the Hollins & Co. syndicate of New York. The deal was effected by James Campbell, broker, of this city, by purchase from Seligman & Co. and Ladenburg, Thalman & Co., of New York. As the Hollins & Co. syndicate control the Laclede Gas Light Co. and the United Electric Light and Power Co., it naturally follows that the Laclede Gas company will control the Municipal Electric Light and Power Co. The result of this will probably be a combine, if not an actual consolidation of the United

Electric Light and Power Co., the Municipal Electric Light and Power Co. and the St. Louis Illuminating Co. This will place the Laclede Gas company in absolute control of all electric light companies in the city, except the Missouri Electric Light and Power Co. (Westinghouse system). The St. Louis Illuminating Co. (of which James Campbell is president) will hold an election December 31st, the object of which is to increase their capital stock from $100,000 to $500,000. The object of this increase of capital stock is not made public, but it undoubtedly has some connection with the combination. At an election yesterday James Campbell and John P. Kelly, of St. Louis, and Elish Dyer, of New York, were elected directors of the Municipal Electric Light and Power Co.

The Municipal Electric Light and Power Co. finding that they can not finish their plant in time to light the city after January 1st, 1890, have asked the city legislature for ninety days extension of time. The matter was referred to the board of public improvements, who decided that no such extension could be granted. This leaves the Municipal Electric Light and Power Co. in a predicament. That is, they will have to pay the city a fine of $500 per day until they light the city with arc lights. The Municipal Electric Light and Power Co. will probably make some arrangements with the Laclede and St. Louis Gas Light Co.'s for continuing their gas lighting until they can finish their plant.

The Laclede Gas Light Co. finding it impossible to finish their electric light plant in time to begin lighting the north end of the city on January 1st, 1890, are installing a temporary plant at the old Western electric station of the United company, corner of Second and Franklin avenue. The instalment consists of two Heisler alternators of 450 30-c. p. capacity for lighting the alleys, and one Brush alternator of 600 16-c. p. capacity for lighting the city buildings.

The Missouri Electric Light and Power Co. are putting in two batteries of Babcock and Wilcox boilers of 500 h. p. each, and two 3,000 light Westinghouse alternating dynamos. This company has nearly everything in readiness to begin their incandescent lighting in the south end of the city, and will be able to fulfill their contract promptly on January 1st, 1890.

On account of the supposed electric light and gas combine, the House of Delegates at their last meeting passed a resolution for the appointment of a special committee to investigate as to whether or not the gas and electric light companies have formed a combination for the purpose of putting up the price of gas and electric light and power.

The St. Louis Board of Fire Underwriters notify the public that on account of numerous accidents and increased number of fires, caused by improper wiring, the board have instituted an inspection of wiring and fittings of buildings. The board will issue certificates, free of charge, for all work done according to their rules, and request all parties entering into contracts for wiring to notify the board of such work before the work has progressed.

The Short Series Electric Railway has been delayed in completion, but it is expected to begin operation next week. Mr. Short and his associate, Mr. Adams, are here attending personally to the final details of fitting up.

The Union Depot Street Railway Co. have finished laying rails on their new division from the corner of Gravois avenue on California avenue to Gyer avenue and Jefferson avenue. This division is to be operated by the Thomson-Houston overhead system.

The St. Louis and East St. Louis Electric Railway (Thomson-Houston system) is now in successful operation. The management are planning for an extension of their line to the National Stock Yards, and will duplicate their power plant at once. The city of East St. Louis has granted them a franchise authorizing this extension.

The Citizens' Electric Light and Power Co., of East St. Louis, organized last October, are installing 120 Wood arc lights and 500 Slatterly incandescent. The work of installation is being done by the Fort Wayne Electric Light Co.

D. B. Alexander, principal owner of the Belleville street railway, has been granted the privilege of changing to electric power. He has also asked for a franchise in East St. Louis, and intends to extend his electric railway from Belleville to East St. Louis, making connection with the St. Louis and East St. Louis Electric Railway. Topeka, Kan., parties are interested in the enterprise.

The Electric Railway Light and Power Co., of Topeka, Kan., have been granted a franchise by the city council of Sedalia, Mo., to build an electric railway some four miles in length, extending from the centre of the city to the water works. The work of installation is to be completed in twelve months.

The Southwestern Electric Engineering Co. were incorporated November 25th, with a capital stock of $10,000. C. J. Briner, A. Irvine and C. R. Meston, shareholders. They represent the Brush Electric Co., and are doing a large amount of wiring for them.

St. Louis, Mo., December 20, 1889.

.... It is not given even to a Newton to create an absolutely new light.—*S. P. Langley.*

PITTSBURGH.

The Pittsburgh and Manchester Railroad Co. to Abandon Horses.—A New Bridge from Pittsburgh to Allegheny.—The Allegheny Electric Light Plant.—The Pittsburgh, Allegheny and Manchester Electric Street Railway Co. Chartered.—The Sprague System to be Used on the Pleasant Valley Line.—Other Street Railway Notes.—The Star Iron Tower Co., of Fort Wayne, to Supply the Towers for Allegheny.—A New Arc Light System by the Westinghouse Company.—An Electric Club in Pittsburgh.—Further Electric Railway Notes.

The Pittsburgh and Manchester Railroad Co. has at last decided upon changing the present motive power of its road, viz., horses —and transform the road into a cable or an electric road. As has been previously stated in this correspondence, the company had to combat numerous difficulties and obstructions to this change. The chief obstacle was the Suspension Bridge, an old structure which spans the Allegheny river from Sixth street, Pittsburgh, to Federal street, Allegheny. A few days ago, however, the directors of the street car company met the directors of the Bridge company for the purpose of discussing propositions, looking to a practicable plan of operation for permitting the Pittsburgh and Manchester Railroad either to lay a cable or electric wires across the bridge. The meeting was fortunately successful, and the result is that an entirely new structure is to be erected in place of the old Suspension Bridge. The new bridge is to be so built as to accommodate either a cable or an electric road. The bridge is to have a double track for cars, a double track for ordinary vehicles and on each side a foot walk. About $160,000 are to be expended in construction, and it is predicted that the new bridge will be one of the finest structures of its kind in the country.

The Allegheny electric light plant is to be hastened towards completion, and it is expected to be in operation by next June. The plant is to have a capacity of 3,000 lights, Westinghouse alternating current system. Ground was broken for the power-house a few days ago on Braddock street, Allegheny City.

A charter was granted a few days ago to the Pittsburgh, Allegheny and Manchester Electric Street Railway Co., the incorporators being John H. Dalzell, A. M. Neeper, G. A. Hill, John D. Nicholson and W. T. Mustin. Inquiries made as to what the object of this charter were, brought out the information that the Pittsburgh and Manchester Railroad Co., which operates a regular net of street car lines between Pittsburgh and Allegheny, will adopt a system of electricity on the Rebecca street line, which is a branch of the main line.

Work on the Pleasant Valley street car line is now rapidly progressing and the directors of the company promise the citizens now that the electric cars will be running by the first of January. This is the company which is about to adopt the Sprague system of overhead wires. Twenty-five cars are expected to arrive here by the first of the year.

A new feature in connection with the working of this road is that the motor men and conductors have contracted with the company for a work-day of nine hours. The rate of wages will be on a basis of 20 cents per hour; any extra time called for in case of emergency to be paid for at the same rate. It is said that the company will call upon the men to work longer hours on Sunday.

The stockholders of the East End Passenger Railway held a meeting a few days ago in the Chamber of Commerce, and the sale of the property, franchises, etc., of the company to Mr. T. A. Gillespie was formally effected. Mr. Gillespie is the treasurer of the Central Traction road of this city, which runs from the lower part of Pittsburgh to the East End, and it is thought, that inasmuch as the East End Passenger Railway Co. owns the franchises for a road to Wilkinsburg, the Central Traction Co. bought them to extend its own line. Electricity is to be used on the new road, which is expected to be finished within a year.

The contract for furnishing the electric towers for Allegheny was closed last week between the Westinghouse Electric Co. and the Star Iron Tower Co., of Fort Wayne, Ind. The contract calls for the completion of all the material within 90 days.

The Westinghouse Electric Co. has just completed an entirely new arc light system, which is claimed to embrace many improvements and advantages. The dynamo is reported to be thoroughly self-regulating, maintaining constant current under any changes of load from one lamp to its full capacity. The dynamo is not only automatic in its regulation, but it is said to exhibit a distinct gain in efficiency over the results hitherto attained in commercial dynamos.

In addition to the dynamo, however, the system has also an entirely new arc lamp, for which similar gain in efficiency is claimed. A principal point among its features is an economy in carbons, which are claimed to last two or three times as long as they do in the present general practice. The mechanism of the lamp is simplicity itself, and its regulation is automatic in every particular.

A social organization is about to be called into existence in Pittsburgh, which will have for one of its chief objects the furthering of the interests of the electrical fraternity and the study of the comforts of the traveling electrician. The club is being established in the Westinghouse building in this city, the gigantic nine-story structure in which the offices of the various Westinghouse interests are situated. When this building was erected the ninth floor was at once arranged so as to make it suitable for the demands of commodious club quarters. The suite of apartments contains a very comfortable kitchen, pantries, closets, etc., a large room for a library, a barber shop, a billiard hall, two dining-rooms, a reception room, a couple of bed-rooms and offices as well as bath-rooms.

The main object of the club will be to afford the officials and clerks, of which there are about 200 employed in the building, a place where they may meet socially and where an opportunity will be afforded them to congregate daily for luncheon. An efficient steward will be engaged to look after the culinary requirements of the club members. Once a month it is proposed to have the members assemble during the evening for the entertainment afforded by scientific discussions or lectures. It is also intended to be the head-quarters of traveling salesmen of electric companies, who will be invited to partake of the hospitality of the club while in the city.

The organization will be duly incorporated and a charter has already been applied for. The chief promoters of the club, as far as has been learned, are Mr. Chas. Payne, the vice-president and general manager of the Philadelphia company; Mr. John Caldwell, the treasurer of the Westinghouse Electric Co.; Mr. H. M. Byllesby, the vice-president of the Westinghouse Electric Co.; Mr. Chas. S. Pease, the general superintendent of the same company; Mr. A. T. Rowand, the secretary; Mr. W. L. McCullough, the auditor; Mr. R. D. McGunnigle, the secretary of the Allegheny County Light Co.; Mr. G. H. Blaxter, the general manager of the Allegheny County Light Co., and several other gentlemen prominently connected with the many Westinghouse interests. It is expected that about $10,000 will be spent to fit up the club, and Mr. George Westinghouse, Jr., will be a liberal patron of the club.

A quiet little row has been in progress in this city for some time between the Squirrel Hill Electric Railway Co. and the city authorities, over the right of way given the company to pass over a portion of Schenley Park, by Francis Torrens, the agent of the Schenley estate, before the park had been presented to the city by Mrs. Schenley. Several meetings have already been held to settle the trouble amicably, but so far all efforts have been unsuccessful.

The rapid transit fever, which has now been raging in this city for over a year, resulting in the transformation of all street car travel, has broken out again on the south side of Pittsburgh. It is contemplated there by a number of prominent capitalists to build an electric road from Mount Washington to West Liberty, a distance of several miles. It is expected that the road will cost about $400,000.

The Second avenue electric road—Thomson-Houston system—is to be running by the first of the year.

PITTSBURGH, December 19, 1889.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

THE LAW OF INVERSE SQUARE.

[112.]—In the November number of the ELECTRICAL ENGINEER is an article on "The Law of Inverse Square."

The author attempts to prove that all central forces must vary inversely as the square of the distance, and bases his proof on the *assumption* (which he fails to mention in his summary) that

$$\frac{dX}{dx} + \frac{dY}{dy} + \frac{dZ}{dz} = 0$$

is simply the analytical statement of the fact that there are no centres of force" where this equation holds.

This is purely begging the question. Laplace first proved this theorem by *assuming* the law of inverse squares; and neither Green, Gauss, Maxwell, Thomson and Tait, nor any other writer that I know of, has proved this theorem without this assumption. It will not do to prove the theorem by the law and then prove the law by the theorem.

The author writes, with regard to Maxwell's experiment on the law of electrical forces:—"It is assumed that the force has a potential, from which it follows that in the space around the conductor the equation of Laplace holds true." This is clearly an error. Forces which vary as *any* function of the distance have a potential (Maxwell, Elect. and Magn. §70); but only forces varying as the *inverse square* of the distance satisfy Laplace's equation, as any one can readily verify for himself. Maxwell's experiment proves what he intended it to:—viz., the law of inverse squares for electrical forces. HARRY FIELDING REID.

CASE SCHOOL OF APPLIED SCIENCE,
PHYSICAL LABORATORY, Cleveland, O., Dec. 4th, 1889.

BADT'S INCANDESCENT WIRING HAND-BOOK.

[113.]—In the December issue of the ELECTRICAL ENGINEER, I notice a review of my little "Incandescent Wiring Hand-book." In his reference to the book the writer of the review states that I have made a serious mistake in developing formula vi., and shows how simple is the formula which he thinks should be substituted. To my mind this criticism indicates that the critic is not a *practical* electrician. In the first place, my formula is not more complicated than his if you eliminate the constant and simply write the formula as on page 62:—

$$d^2 = N \times D \times K.$$

It seems to me perfectly clear that a wireman will not make a calculation for more than one kind of lamp in planning work for a single plant; therefore he will calculate the constant first and apply for all his subsequent calculations simply the formula mentioned above.

But in the second place, even if it be admitted that the formula which I employ is more complicated than that proposed in your paper, I would still object to the use of the latter.

Almost every contract for electric lighting states *in percentage* the permissible loss in conductors and this method of statement has come into such general use that it must be recognized. Any table, therefore, expressing the loss must give it in *percentage* and not in *volts*. For a great many reasons this plan is very desirable, but I will mention a single illustration only. Suppose, for example, two companies bid on a plant, one on the 110 volt system, the other on a 75 volt system. If they both state that they will wire the building for five volts loss, it is evident that they are making entirely different proposals. If, on the other hand, each would state in its proposal that the total percentage of loss in the wires would be five per cent. of the total energy, the statements would be clear and fair in comparing the two cases.

I will further say that my formula, whose absurdity is so apparent to the gentleman who wrote the criticism in your valuable paper, is used by the engineering department of one of the three largest companies installing incandescent plants, and, therefore, is familiar to a great number of wiremen.

I may also be pardoned if I add that not a line in my little hand-book was published without having been subjected to the most severe criticism, not of office electricians only, but of practical incandescent wiremen. Whenever any one of these gentlemen whom I consulted found fault with what I had written or said, I took particular pains to review the statement and put my ideas in such language as seemed perfectly clear. I have tried to satisfy in this little book not office electricians who handle algebraic formulæ as easily as a boy his toy, but practical incandescent wiremen whom I hoped to educate to a higher standard. I think the criticism on these points is without foundation. I have changed quite a number of points in the second edition now printing in accordance with suggestions which I have received from a large number of gentlemen in the United States and abroad, but I did not see fit to change any data according to the suggestion of the gentleman who wrote the review referred to above.

There is one word which I may say concerning my assumption that the resistance of a mil-foot of copper wire was 10.79 ohms. The only error I committed in this respect was that I spoke of "pure copper." I should have said "commercial copper." We do not handle pure copper wire, and for calculating the loss of energy in copper wires in practice, we ought to assume a higher resistance.

You would very much oblige me by giving this reply space in the next issue of your valuable paper. F. B. BADT.

A STROKE OF LIGHTNING.

[114.]—It is remarkable with what persistency lightning avoids well arranged rods. The 25 buildings on the 46 acres of Lafayette College, have never been struck although some of them are very tall and all of them are on high ground. Pardee Hall, the seat of the Scientific School, was destroyed by fire in June, 1879, leaving a ragged mass of ruins. During the first storm after the fire these ruins received a terrific stroke, the lightning seeking the earth through a broken water conductor. Since rebuilding, there has been prefect immunity. On the same plateau with this building is a large community, with houses not so generally protected. The lightning frequently strikes here; also at the base of this elevated level where the main body of the town lies—150 feet below—lightning strokes are not infrequent.

This summer, a case occurred which seems worthy of record. No. 305 Monroe street, is one of a group of five dwellings situated on College Hill. The group is isolated—having nothing on the north, for a distance of an eighth of a mile, perhaps, at which point a spur of Chestnut Hill rises suddenly to a height of 500 feet; on the east is a narrow street, on the opposite side of which are two small houses; on the south there is a clear view for two blocks, and on the west, 150 feet distant, a large house protected with a rod. In the immediate neighborhood there are several other protected houses. The house struck is the western half of a "double" building; this and the other dwellings being separated by alleys three and five feet wide. It is the middle one of the group of five. No one of the five is rodded. It is not the most conspicuous by any means, the adjacent corner house being higher and having projecting ornaments on the roof. It extends a few feet further north than the others. The back part of the house, where the damage was done, is lower than the front. The point of attack was the ridge adjacent to a brick chimney which was pouring out hot gases from a very hot stove at its base, in the kitchen. The chimney was not disturbed. The charge tore the slates from the roof, split a rafter and made an earth through the tin water conductor leading to a cistern near by. At a point where the vertical pipe enters the funnel shaped vessel, the tin was perforated, the burr pointing towards the earth. It is well known that hot gases are good conductors, but here the charge avoided the column and the comparatively high brick chimney and struck the roof at a place probably not a dozen inches from the point of contact between the chimney and brick work.

Those who have performed the experiment of placing various pointed, rounded, and hot objects—like a lighted candle—on the metal plates of an air pump connected to earth and one pole of an induction coil—the other pole being joined to a tin disc suspended above, have seen just such a phenomenon as that cited above.

MULTIPLE TELEPHONY.

[115.]—It may be of interest to your readers to learn something more of the late interference case between J. J. Carty, John A. Barrett and myself, for a system of multiplex telephony which was pending for over two years in the United States Patent Office, and which interference was only recently dissolved by the question of priority of invention being decided in my favor.

This system contemplates the duplexing of long-distance telephone lines so that two subscribers or a subscriber and a central office operator at one end of a trunk line may communicate with two subscribers, or a subscriber and a telephone operator at the other end without interference. This is accomplished by using a metallic circuit between the two central offices and by connecting a subscriber's line to each end of said metallic circuit. The trunk line operators are supplied with differentially wound transmitters and receivers. One coil of each transmitter and of each receiver is inserted in the outgoing wire of the metallic circuit and the other coils are inserted in the return wire. Each transmitter has a local circuit common to both induction coils and each of said induction coils is provided with an adjustable core for balancing the two branches of the metallic circuit.

By "connecting up" the receiver coil and the transmitter coil of one branch of the metallic circuit, with a pole charger, the trunk line instruments may be made to actuate and respond to either system at pleasure. That is, when the pole charger is turned in one direction, that trunk line instrument is in touch with the other trunk line instrument only, and when the pole charger is turned in the opposite direction, that instrument is in touch with the subscribers' instruments only. Hence the two systems are independent of each other, and may be used simultaneously and without interference. In one case the telephonic currents traverse the metallic circuit in the same direction, and in the other case the currents move in an opposite direction. In this way the working capacity of trunk lines may be doubled and the expense of operating said lines proportionately diminished.

NEWS AND NOTES.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

MEETING OF DECEMBER 17, 1889.

Professor Harris J. Ryan, of Cornell University, read a paper on "Transformers." (See page 7.)

DISCUSSION.

Mr. Townsend Wolcott—Did I understand Professor Ryan to say that the loss of energy is necessarily less where there is mechanical vibration?

Professor Ryan—It seemed to us to have been so in this transformer; but we are not sure of it.

Mr. Wolcott—On the supposition that it is so, where does the energy come from? The idea is that the reversal of polarity of the iron absorbs a certain amount of energy in any case; is it not?

Professor Ryan—The idea, I suggest, amounts to this: that the energy that was taken up in shocking that iron was less than what was saved in the hysteresis. That is, the hysteresis was made less by a greater amount than the energy that was spent in shocking the iron.

Mr. Wolcott—That is the way I understood it; but is there any explanation why that should be so?

Professor Ryan—Not that I know of. I have not thought of the matter to any great extent, or further than I have indicated.

Mr. Nikola Tesla—Professor Ryan has said that the form of the primary current wave departed considerably, in certain conditions, from that of the primary electromotive force; and he also stated to what he thought this departure due. I think that this departure of the primary current wave from that of the impressed electromotive force is due, to a considerable extent, to the conditions of the secondary circuit of the transformer, and I regret that Professor Ryan has not shown in the secondary an inductive resistance instead of the lamps. I think that then there would have been found a still greater departure of the primary current from the primary electromotive force. If we close the secondary circuit through a non-inductive resistance, such as lamps, it diminishes the lag of the primary. If we close it through an inductive resistance it increases the lag of the primary. In this way two effects may be produced; first, the primary current wave will depart more or less from that of the electromotive force; second, the secondary electromotive force will lag behind the primary electromotive force, as Professor Ryan has found.

Professor Ryan—I would like to ask Mr. Tesla how he would produce that inductive resistance in the secondary circuit?

Mr. Tesla—When you close the secondary circuit through the resistance suppose that you put a coil of wire in the circuit instead of the incandescent lamp.

Professor Ryan—Would you not be increasing the hysteresis effect in that way? It seems to me that then just what you say ought to follow? Of course it should be understood that stress is laid merely on the fact that there is a certain component at all times flowing to keep up the magnetism; but, aside from that, whatever current passes is merely the opposite of that which passes the secondary circuit.

Mr. Tesla—You stated that this departure was due only to the hysteresis.

Professor Ryan—Suppose that you use hysteresis in the secondary circuit, and thereby augment the irregularities of the primary circuit; is it not, after all, ultimately due to the hysteresis?

Mr. Tesla—But suppose instead of the incandescent lamp you use a coil of inductive resistance, which would take the same current as the lamp?

Professor Ryan—When you use any device by means of which you introduce hysteresis in a secondary circuit, do you not greatly augment the displacement of the primary current?

Mr Tesla—Of course as we load the secondary with lamps the primary comes closer and closer to where it ought to be; and I think if you had made a trial with an inductive coil in the secondary circuit instead of the lamps it would have shown some interesting conditions.

I believe Professor Ryan stated that the secondary electromotive force commenced at a given point to lag behind the primary electromotive force?

Professor Ryan—Of course it is gradual.

Mr. Tesla—Have you not noticed, for instance, when this takes place, that it began suddenly?

Professor Ryan—No; I have not noticed that it began suddenly.

Mr. Tesla—I should say that when the secondary circuit has a different retardation from that of the primary circuit, then this condition begins. That is to say, if you have a primary coil, and you pass the current through that coil, and you have the secondary circuit closed, you then observe a certain lag of primary current. Now, if you add in the secondary circuit an inductive resistance, you can cause a still greater retardation in the primary. And if you diminish the retardation of the secondary, by inserting lamps, you diminish the retardation of the primary circuit to a greater extent than that of the secondary; thus in both cases causing the secondary electromotive force to lag behind the primary.

Professor Ryan—I would like to say that Mr. Merritt and I intend to continue our work in this line, but, of course, we wish to vary the circuits upon which we experiment. As soon as we have done this work on the transformers we expect to take up the action of the condenser in all its relations to circuits possessing inductors, and to circuits not possessing inductors; and will test this matter which Mr. Tesla has just spoken of by working a coil in the secondary circuit, instead of a lamp. I think that a great deal is brought out in this way; and that one would be able, by careful study, to predict fairly well what would take place by varying the conditions.

Mr. A. E. Kennelly—There are two points about which I would like to ask Professor Ryan. One is with reference to that very distorted curve that we see upon the first sheet, representing the values of the electromotive force and currents when the secondary is open. I understood Professor Ryan to say that the square root of the mean square of the primary current corresponding to that distorted curve did check with the average of the square roots of the ordinates as compiled in the series. Now that statement, supposing it to be rigidly accurate, is tantamount to an assertion that the primary curve, which looks so distorted, has really the position of two sine curves; because, if I mistake not, the sine curve is the only curve which possesses the property that the square root of the mean square should represent that average. It would therefore mean this: that the primary current, starting under the impulse of that primary impressed electromotive force (which we will assume to be a true sine curve) shall meet with an opposing force, which is of itself a sine curve. I think it is important to know whether that is so or not. I think it would also be interesting to know how far the observations before us show whether the curve of the impressed electromotive force is of a true sine nature or not. We know that it approximates to it in a great number of cases; and we know also that in alternating current dynamos the curve is by no means of a true sine type. It is fundamental in the whole subject we are studying to know how far the deviation is from the theoretical sine curve.

The question of hysteresis is of very great importance in every point of view. We know that we can measure the amount of energy which a converter absorbs in a given time; and we can measure also the amount of energy that it delivers in a given time. We have then to deal with the remainder of energy absorbed by the converter uselessly; and this is to be found, first, in a purely frictional resistance to the current, whereby the energy is transformed into heat; and second, in the effect of the magnetism there is in the current producing the magnetic lag. It is of the very highest importance that we should be able to separate those two forces; and the paper before us gives very important suggestions by means of which we can carry that differentiation into effect. The Foucault currents can be reduced sufficiently by diminishing the cross-section at any one point; and we know that in good transformers such currents can be reduced to a minimum; but what we do not know is the quantity of energy which is being absorbed in the hysteresis under the conflicting conditions which are perpetually occurring.

In civil engineering we are brought face to face with the wonderful fact that a very large portion of its application and design lies in the general knowledge of the properties of the molecules of iron in the different conditions in which iron is used; and the mystery grows more and more when we remember that in electrical engineering it is not so much the mechanical properties of iron, in the mechanical engineering sense, as it is the electrical properties of iron, which concern us, and which vary perpetually in every design for apparatus; because, after a piece of apparatus has passed from the stage where the wonder is no longer new, then the question comes: How much can we economize and save out of a given mass of iron or copper? And the question, which is coincident with that, of how much we can save, or waste of hysteresis in iron becomes of greater and greater importance.

In hysteresis we have two distinct things to deal with; first, we have the fact that the iron will not return immediately to its previous condition after some magnetic effect has been impressed upon it; and, secondly, that it has a frictional resistance, and cannot instantly obey the reversed force. In all slow working transformers, in all pieces of apparatus where the changes are slow and steady, we can generally neglect what is called the frictional hysteresis due to speed, and simply deal with the static hysteresis; and it becomes of the very greatest importance that we should be able to distinguish between the statical hysteresis and the physical hysteresis. With regard to the question asked as to the effect of mechanical shocks on hysteresis, I think I may suggest a possibility, namely, that it is simply a question of how the magnetism which has been left after a given impulse can be shaken out; and if you can shake that magnetism out by any means you will have that hysteresis destroyed. If you will study the hysteresis chart before us you will see that the area of the curve represents actually the amount of energy which is being consumed or delivered from the cycle in the iron through its magnetic effect; and if you can prevent that taking place that lag would disappear.

I think the question of the differentiation of the physical hysteresis from the static hysteresis is one which has gone beyond experimental methods, and has become one of very great importance; and if words were necessary to recommend its importance still further, is it not enough to consider that apart from practical considerations it has also a very important scientific bearing; because, by the way in which magnetism acts upon iron (the most completely magnetic substance we find in nature) the more readily can we guess at the principles which underly the whole phenomenon of magnetism; and the more completely can we discriminate the different conditions under which that iron acts, the more truthfully shall we able to guess at the conditions which nature imposes upon that iron

Dr. Wm. E. Geyer—I would like to ask Professor Ryan (if he will be kind enough to turn to the chart showing the primary electromotive force) if any peculiarity was ever noticed about half way up in the curve of the primary electromotive force; a sudden departure from the smooth curve.

Professor Ryan—Yes; as I think of it now.

Dr. Geyer—Last May and June there was made, under my general supervision, a very similar experiment, where, however, we used a condenser, and discharged the condenser through a galvanometer, and in that way measured the relative dimensions of the electromotive force. We also got curves which were very smooth indeed (we took points more numerous than those that are drawn on the chart before us), until we got to a point about half way up, where we obtained results which at first we thought irregular and accidental. We skipped that part of the curve and went further up, when again it was extremely regular, until we got down on the other side to about the same height, where again the irregularity began. The irregularity was so precise that it meant to my mind that it was not a simple accident of the experiment. We then took especial pains to determine points extremely near together just in that region, and persistently obtained a very decided jog in the curve; that is, a sudden upward motion, and a sudden downward motion, at the end of which the perfect regularity of the curve was resumed; and on the other side again there was the same irregularity, and the same jog on the lower curve again. I have not found any satisfactory explanation as to the cause of it. If any could be offered by any one present it would be very interesting. I might mention in addition that when these same curves were determined on an open circuit, or on a non-inductive resistance, the irregularities were not noticed. They were only noticed when the transformer was a part of the main circuit.

Mr. Tesla—May I ask whether the machine was run at a constant number of alternations all the time?

Dr. Geyer—The machine was run at constant alternations—the regular commercial speed.

Mr. Tesla—I think if the number of alternations had been varied, greater irregularities would have been observed. I think it will be found that if a higher number of alternations had been chosen, the irregularity would have been more pronounced, until a certain limit was reached. I have run them as high as 150,000 alternations per minute. Where the alternations were very low the irregularity disappeared; but when the same number of alternations, with a longer magnetic circuit in the transformer was employed, they would again appear. So that, as I know that the magnetic lag was varied by the length of the magnetic circuit, I assume that this was the cause of the irregularity. Mr. Kennelly has very ably, and rightly, brought up the importance of the study of hysteresis. I think this is a field in which we should all work and achieve considerable improvement; so much so that certain of my experiments have been rather surprising; and in investigating the cause of the lag of the iron we will find the experiments not only of value to investigators but of real value to us practically.

Mr. Joseph Wetzler—In reference to the remarks made by Dr. Geyer as to the cause of the notch in the curve, it seems to me that it might principally be due to irregularities in the nature of the field. The field poles may have different intensities over different parts of the surface, so that if more strongly magnetic all around the edge than at the centre they would produce an irregular field, which would cause a corresponding effect in the current produced; so that all of the curve would not be regular.

Mr. C. O. Mailloux—I am inclined to believe that the theory advanced by Mr. Wetzler is the correct one; and I think that the notch in the curve is accounted for by the dynamo, rather than by the reaction of the converter upon the impulse. The fact is, that in a dynamo we never have a uniform distribution of the lines of force, from the very fact that towards the centre, the lines of force are more dense than in the area which is contiguous to the edges. The consequence is that when a coil is approaching the edge of the pole it is approaching a spot where the lines of force are more dense; and after it has passed that spot it finds itself in a place where the lines of force are not so dense. It again meets towards the middle of the pole, a place or period where the lines are denser; and again as it comes to the outer edge, a place where the lines of force are not so dense. Now, if you bear in mind the fact that the lines of force are merely the exponents or indicators of the condition of the magnetic medium, showing that there is a highly elastic substance under great stress or tension there, then we may replace those lines of force by elastic substances; and you will find on theoretical reasoning that you would naturally expect that the action of the wire, the moment that it begins to have the current in it, would be reacted upon the lines of force and displace them at that point. We know that such is the case in continuous current dynamos, but not with alternating currents. We know that the lines of force are distorted and thrown out of their course by the action of the current in the armature itself. Professor Elihu Thomson has shown by experiments that there is such a crowding effect on the lines of force that, as a matter of fact, the area of the coil, or the contour of the coil, encloses a smaller area of them than the area of the pole possesses. I should imagine that the notch in the wave of the impressed electromotive force would be due to the fact that, as the current approaches, it first meets with an obstruction which is too stiff for it to bound over, and therefore immediately quits the line of force, creating a high tension, which produces a higher electromotive force. Then we come to a place where the field is more uniform, and consequently we get the action which we would naturally expect—a current more nearly uniform, and at a rate more in accordance with some fixed law. Then as we come to the outer edge we must pass through another crust of the lines of force, and we would naturally expect to find another big break and a slight up-wave. Pursuing the same reasoning you will find that this would take place just exactly as Mr. Geyer has found by experiment; and that the speed at which the alternations occur have a great deal of influence upon that. I should have expected that the loss of force, being like all electric substances, more brittle to a rapidly acting force, would show that effect more perceptibly at higher alternations than at lower ones.

Mr. Tesla—Just a word before you pass to another subject. That opposition which was alluded to as occasioned by the dynamo machine might not have its cause in the machine; but that very kind of opposition may exist in the transformer itself; and there is where I believe it does exist. I was some time ago engaged in some work in getting direct currents from an alternating current; and I found that I was able to produce a preponderance of current impulses in one direction over those of another; and then I found that under certain conditions an opposition appeared, exactly as was stated by Mr. Mailloux in regard to the dynamo machine; and that such conditions can be brought about; and that they depend greatly upon the iron, on the number of alternations, and the length of the magnetic circuit. Imagine, for instance, that you have in the magnetic circuit of the transformer magnetism in one direction set up; certainly if such magnetism exist it will oppose the passage of a current of a certain direction; and in this way a certain modification of the curve would be brought about.

Mr. Mailloux—I am very glad that Mr. Tesla spoke of that. I might have gone farther, and said that undoubtedly the same phenomenon would occur in the transformer core itself, and that there would be changes of magnetism there under different circumstances; that inasmuch as he has so much more ably explained it than I could, I need not refer to it again. The only other point I wish to advert to is in connection with some of these curves. I would like to ask Professor Ryan whether he has taken the trouble to follow the concomitant variations of the values of the inductance; that is to say, the instantaneous values that we are supposed to get for the inductance at different variations of the electromotive force; so that we might be able to get a means of comparison between theory and practice. As we all know, the theory of the transformer is one thing, while the practice is another thing, quite remote and apart from it; so much so that the theory, although it is not yet complete, is already behind the times. We know also that that innocent looking symbol designated by L, which represents the inductance in a transformer circuit, does not happen to do so in the transformers which we use in practice. It does so on paper, and in mathematical equations, and also in transformers which have no iron. Now it would have been quite interesting if Professor Ryan had undertaken either to calculate or derive the value given for the inductance; so that we might from that calculate the impedance of the circuit; or, in other words, that spurious resistance factor by which we must multiply the square root of the current in order to get the energy that appears in the circuit.

Professor Ryan—If I have understood Mr. Mailloux's question I will answer it in this way: That if you take what is the accepted theory of the transformer up to date, and which assumes always, I believe, that the relation of the current and magnetism of the iron is the same in an up curve, as it is going down; taking that theory as it has been elaborated, and the suggestion made by Lord Rayleigh about a year ago, that is to say, taking the transformer and observing the relation of the magnetism of the iron corresponding to any particular number of ampere turns going up and coming down, to modify that theory (because it is not always the same), and when you have measured the difference that exists in going up and coming down, you will get exactly the state of affairs that are here found actually to exist. The suggestion that was made by Dr. John Hopkinson in a note published in the Proceedings of the Royal Society a few years ago, made a faint suggestion that if you assume *this* curve, and substitute for that curve a curve as modified by the values which you obtain in hysteresis, you will get precisely this state of affairs. One thing more with regard to the method by means of which you can express the exact shape of those curves mathematically, and therefore proceed by means of mathematical investigation, and by means of the impressed electromotive force that we have here given, to find what it is, and what should follow: I will say that Mr. Merritt has carefully analyzed the properties of those curves, and has shown that the impressed electromotive force curve is made up, in the first place of a sine curve in unison with it, and another curve of the third order running along like *this*, and finally one of the fifth order; and if we should carry it one further we should find with it one of the seventh order—in odd orders, the even orders having disappeared, or else the magnetism would be heavier on one side than on the other. But matters of that sort are very technical; and I did not think that these curves, representing the constituents of these various curves, would be of much interest, or I should have brought them with me.

Mr. E. G. Acheson—I understood Dr. Geyer, in speaking of the notch in the curve, to say that he obtained it only when he had the transformer in. That being the case it could scarcely be due to the machine.

Dr. Geyer—The notches were not obtained when the dynamo was run on an open circuit.

Mr. Kennelly—In that case, I venture to say that it must be due either to the magnetic lag, or else to a variation in the self-induction. If the processes of self-induction were variable it might be expected. With such variations it is probable that such kinks would follow.

Dr. Geyer—Am I right in understanding Professor Ryan to say that the efficiency of the transformer was 85 per cent.?

Professor Ryan—Eighty-six and six-tenths per cent. when working with ten lights in the secondary.

Dr. Geyer—Was that efficiency tested also in some other way?

Professor Ryan—No; it merely came in as a secondary matter.

Mr. Mailloux—It strikes me that Doctor Geyer knows more than he wants to tell us about the transformer tests. I have been told that some extensive work has been going on at Stevens Institute, and it would be interesting to get some information about it.

Dr. Geyer—What I could say about it has already been published in the journal of the Franklin Institute. It would have been read before this Institute, except that it came late last year, in June, before the summer vacation; and there were so many other papers that it was crowded out. The other tests we made, are very much like those of Professor Ryan, except that we used a condenser as a means of measuring the electromotive force; and we worked a 20-light transformer instead of a 10-light; and the mechanism for taking off the instantaneous electromotive force was slightly different. It is hardly worth while to go through details, as a larger part would be repetition. I have not seen anything in Professor Ryan's charts that differs from those that we obtained. So far as I can see, the results are essentially of the same nature.

The Chairman (vice president T. C. Martin)—I understand that Mr. Stillwell, who is Mr. Shallenberger's associate, is here, and if he is moved to speak we would be glad to hear from him before the meeting is closed.

Mr. L. B. Stillwell—The work that Professor Ryan has introduced to-night is in the general line that we have been working on for two or three years. I had not intended to add anything to the discussion, but there is one point that I might mention which may possibly be of interest, and that is, that we have noticed the point to which Professor Ryan referred in the case of a 10-light transformer, wherein he found that the loss due to the iron decreased as the load is added to the transformer. We have observed that this decrease is more marked in the case of a small one. In a 40-light transformer the iron loss is more nearly a constant; and it seems to me that this fact is in the line of the explanation which has been suggested, as to the shaking out of the magnetism, and the consequent decrease of loss in iron at heavy load in small-sized transformers, as larger ones would be somewhat less liable to mechanical vibration.

If I have understood the diagrams correctly, there is one other point which differs slightly from the observations I have made, in which observations, however, I used the divided electro-dynamometer method of measuring the angle of lag. Of course, that method is based upon the assumption that these are sine curves. Applying that method we have found that the lag factor, or co-sine, is somewhere in the neighborhood of 70 degrees; and as load is added to the secondary the factor increases more rapidly, than shown by the curves that Professor Ryan has drawn. For example, with five lights on the secondary I have found that the primary and secondary currents are practically 180 degrees apart, the co-sine of the angle of lag being about 98 degrees. With that explanation the discrepancy may possiby be due to the irregularity of the primary current, as the diagram by Professor Ryan shows.

I will say that we have also quite recently adopted a method of drawing an accurate diagram of the wave E. M. F. The method is due to Messrs. Scott and Morris, of our laboratory. I have not applied it yet, and have not seen it applied to the purpose of noting accurately the form of wave derived from our ordinary machines, since we have been more especially engaged on new types and various experimental work. The method, however, would afford a very ready means of checking up this observed kink in the curve; and I shall take the trouble to make experiments as soon as possible to throw light on that point. The method in question consists simply in mounting upon the armature shaft a wooden disc with a metallic contact at one point in the periphery, this point being connected with one terminal of a voltmeter, while the other terminal of the voltmeter is attached to one collector of the dynamo. A brush that is connected with the other collector touches the metallic point on the disc once in each revolution. By altering the position of the disc we can get a potential reading on the voltmeter proportional to the electromotive force developed by the machine at any given position of the armature, and moving it gradually through 180 degrees we have obtained surprisingly accurate results—the quantity of current through the voltmeter being large and the time being very slow. The cards I have seen made out in the last week are very accurate, and show perhaps 40 points on a phase diagram. I regret that I have none of the cards here, as they might be interesting in connection with the points brought out.

I would like to add one observation, and it is with regard to the observed efficiency of the transformers. It is, of course, understood that the efficiency of a small transformer is necessarily much less than that of a large one. The conditions heretofore have been such as to compel the use of small transformers, but the tendency as we observe it is very largely towards the use of larger ones. This tendency will do away in a great measure with the implied criticism upon the efficiency of the transformer system.

Dr. Geyer—I might say that three years ago, when the then existing methods of measuring the efficiency of such apparatus were very uncertain, we resorted to some heroic treatment of it. We stripped the transformer of its outer coil (which I think has not much to do with its efficiency) and the whole transformer was immersed in kerosene oil, and the transformed current was also used up in a calorimeter, consisting of a jar of kerosene; and then we found that as the load was increased the proportion of heat in the calorimeter to the total heat produced, was less and less as the load was made greater and greater.

Mr. Tesla—Mr. Stillwell has alluded to a method of tracing the wave. I would like to ask the members if any of them have ever made an attempt to find out whether there is a difference when the laminated sheets of the transformer are loose or tight, and if not I wish some one in his idle hours would investigate that; because I have reason to believe that there is a difference when the sheets are tight and when they are loose. Of course, it might be due to the imperfect contact of loose sheets, which would tend to diminish or increase the circulation of Foucault currents.

Adjourned.

ELECTRICITY AND LIGHT—"EXCELLENT FOOLING."

It is beyond doubt that if the world were obliged to wait till it learned what anything is in its real nature before making use of it, all civilization would vanish. Electricity demonstrates its deadly reality every day before our eyes quite as convincingly as if we knew what it was; and yet the recent discovery that it is identical with light, excepting only the rate of its vibrations, is interesting, although it adds little to the sum of our positive knowledge so long as we do not know what light is. Electricians say that if they can only succeed in increasing the rapidity of the vibrations of the unnamed something, they can give us light directly, without the intermediary stage of heat-production, which consumes an enormous percentage of the power directed to the production of the electric light of the present day. If they can quicken the vibrations till they shall penetrate glass with the velocity of the light vibrations, they will then be able to light up the whole earth. This seems promising, but the promise is tempered by a trifling doubt. What if, after the vibrations of this slow electricity shall be quickened to the velocity of light, the electricians, in the very moment of supreme success, should find that they had left in their hands nothing but the old-fashioned light after all? That would be a mortifying outcome of so much patient toil, and they might in that case doubt whether it had been worth while to go through so much to learn so little. Nevertheless, the course of experimental science must be watched with interest, even by minds held in readiness to suspect in the end a condition of things like unto that of the dog who dropped his piece of meat into the stream in order to seize its reflection in the water.

Certainly if electricity ever shall be quickened into light, this town will become a far safer place of habitation than it is now, when one scarcely ventures to put a latch key into his own door. The worst that could happen to peaceful citizens in that day would be to become "Dark with excessive bright," and excess of light does not seem to be quite so dangerous as excess of electricity. The experimenters may proceed along the line of light, then, unchecked by any criticism of ours. Perhaps, after all, this may be the only way of stopping the ravages of the deadly wire, and if so everybody will help gladly to quicken the vibrations, though the electric companies be left at the end with nothing on hand but a lot of the common, cheap sunlight which now we so carefully shut out. Who knows but if that sunlight should be brought into our houses in tubes or along wires, turned on or off at will, metered, and paid for, our people might not be induced to use it more freely? If quickening the vibrations is thus to result in increased respect for the sanitary effect of light, and decreased risk from the lethal effect of electricity, it is on all accounts desirable that the vibrations should be quickened.—*N. Y. Evening Post*, Dec. 2.

THE FORTH BRIDGE AND THE EIFFEL TOWER.

On Friday, December 6, Mr. Frederic E. Thomasson, C. E., delivered a popular lecture to a select audience, in Worcester, on the above subject. The lecturer endeavored throughout to simplify his descriptions of the details of the two engineering structures by means of a series of elaborately colored diagrams. The lecturer exhibited elevations of the whole Forth Bridge and the Eiffel Tower, to a scale of 10 feet to the inch, so that the audience might easily grasp their relative proportions. After fully eulogizing the great labors and successes of Mr. B. Baker, the lecturer proceeded to complain of Mr. Baker's comparison of the Eiffel Tower with the Forth Bridge. Mr. Baker, he said, placed the tower horizontally, and then found it considerably shorter than one of his own cantilevers. The lecturer stated that a Forth cantilever was composed of two distinct brackets, both alike, and braced back to back above the four masonry piers, with a united length of 1,360 feet; but he held it the only fair comparison to employ two Eiffel Towers, upset them, brace them also back to back at the feet, and put their united 2,000 feet against the other 1,360. In other words, the one tower in Paris, compared favorably with one-half of a cantilever, or Forth Bridge bracket. The Forth Bridge had six such brackets, and he could only accept six Eiffel Towers in comparison. Of course, as a whole, the Forth Bridge puts the Paris tower completely in the shade—still the lecturer maintained that M. Eiffel had shown in his remarkable undertaking more science and neater skill than was displayed in the great Forth Bridge. He drew special attention to the hydraulic jacks placed under the feet of the Eiffel Tower, by means of which it could be lifted or depressed in correction of any tendency it might have had to lean during building.—*Industries.*

STORAGE BATTERY THEORY.

At a meeting of the International Society of Electricians, held in Paris, on the 4th of December, M. Drezwiecki presented a new theory of accumulators in opposition to the usually accepted theory of double sulphation. According to him a hyposulphate of lead is formed which becomes reduced again when the battery is discharged. The enunciation of this theory was received with great opposition, particularly by M. G. Roux, who stated that a hyposulphate could not exist in the midst of acid, and by M. Faure, who thought that the double sulphate theory, with all its faults, was better than the new one. M. Sarna afterwards presented some results of the electric lighting of trains by means of accumulators. He enumerated the various advantages of this system, and gave the average cost on the North of France railway at 0.006 francs per 8 c. p. lamp per hour, or about two-thirds of the cost of the best oil lamps.

ELECTRICAL INDUSTRIES IN THE ELEVENTH CENSUS.

Mr. Robert P. Porter, Superintendent of the Eleventh Census, has issued the following important letter to all persons interested in the electrical industries of the country:—

"I beg to inform you that under the authority conferred by Act of Congress, approved March 1, 1889, Mr. Allen R. Foote, Cincinnati, O., chairman of the Committee on Data, and of the National Committee on State and Municipal Legislation, of the National Electric Light Association, has been appointed a special agent of the census, to have charge of the statistics of the electrical industry. The special agent is authorized to conduct in his own name correspondence relating to this industry, and, under the direction of the superintendent of census, to pursue special inquiries into the condition and tendency of the industry placed in his charge.

"It is the purpose of this office, without seeking data which may be irrelevant or unimportant, to make the statistics of this industry complete and accurate, so that its real condition and true importance may be known and understood by the general public.

It is confidently believed that those who are to derive the chief benefit of the inquiry—manufacturers and central station companies engaged in the distribution of electrical currents for the commercial uses of light and power—will lend their cordial aid to render that result full and reliable. A formal response to the questions of the schedule is all that can be insisted upon, but the superintendent solicits beyond this the hearty co-operation of all persons interested both in respect to furnishing information promptly and accurately and in the suggestion of pertinent and useful lines of investigation. Without such co-operation intelligently supplied, the inquiry must, of necessity, be limited in its value.

"All persons to whom inquiries may be addressed are assured that the requirements of law, that answers to census inquiries shall be treated as strictly confidential, will be faithfully observed. Each employé of the census office specifically makes oath not to disclose improperly that which he ascertains; and severe penalties are imposed for a violation of the obligation to secrecy. Consequently all persons addressed may have confidence that their compliance with the requests for information as to certain details of their business will in no case be followed, either in the report of the special agent or in the tabulation of results, by the disclosure of matters which they properly desire to withhold from publicity.

"The census of 1880 makes no mention of the industry of generating and distributing from central stations electric currents for the uses of light and power. The investigation of this industry for the eleventh census will be the first official census report made on the subject in this or any other country.

"For this reason it is particularly desirable and essential that the investigation shall not only present a correct record of the industry as it exists to-day, but that it shall so classify and arrange the information as to render it serviceable as a basis of action and comparison for all future reports. In view of these facts the importance and value of such an investigation and the official publication of its results should in itself be sufficient to secure from every person addressed a special effort to answer fully and promptly every inquiry. The exhibition of the birth of an industry and its growth to the magnitude of an interest second to none in importance within the short space of a single decade is a marvelous record of progress. In no other industry and in no other country has such a record ever been made."

COLLEGE NOTES.

Harvard University.

On December 2d, Professor Trowbridge delivered a very interesting lecture on "The Nature of Electricity," before a large audience. The lecture was given by invitation of the Harvard Electric Club, which now numbers over 60 members.

Professor Trowbridge began by saying that during the last hundred years there had been three great generalizations in physical science. Two of these, the law of conservation of energy, and the law of gravitation, were of Anglo-Saxon origin; the third was due to a German physicist,—Hertz. This third generalization taught that light and electricity are really the same, deriving their energy from the sun. To it the lecturer wished to call attention, and to repeat in some measure the experiments through which it had been established.

As introductory to these experiments, the lecturer spoke of the researches of Faraday, Franklin, and Henry, and showed how near they came to this discovery. Then photographic views were projected on the screen, showing the oscillatory nature of the discharge of a Leyden jar, and the elasticity of the medium through which it takes place. It was shown that a wave motion can be made to take place between two Leyden jars, and that to do this the jars must be in tune with each other. The analogous phenomena of resonance and the measurement of sound waves, were spoken of. By means of a large tuning fork, a horizontal cord was set vibrating, so as to produce wave motion with a node at the centre. A blind man might pass his finger over the cord and tell how it vibrated; in just that way, Hertz with his loop of wire, or "electrical eye," had found out the character of electrical waves. A reproduction of Hertz's apparatus was exhibited, and some of the experiments performed. It was shown that these experiments confirm the mathematical researches of Clerk Maxwell. In closing, the lecturer projected upon the screen a handsome photograph of the sun's corona, as it appeared in the last eclipse, and noted the apparent north and south poles upon it.

In the various courses in physics there are 236 men, and of these over 200 are pursuing the laboratory courses.

On December 4th, Mr. J. C. Wait, of the Lawrence Scientific School, gave an interesting talk on "Practical Points in Electrical Engineering," before the Electric Club.

At Professor Trowbridge's lecture, an electrical machine made especially for the college by Benjamin Franklin, was shown. It consists of a globe, about a foot in diameter, made of some dark substance, and turned by an elaborate wheel and crank arrangement. It is mounted on large pole-like supports, and covers in all, about 4 x 7 x 5 feet.

Massachusetts Institute of Technology.

Mr. Hollis French, '89, has entered the electrical engineering business, associating himself with two other "tech." graduates, under the name of the Massachusetts Electrical Engineering Co. The object of this company is to act as a mediator between manufacturers and purchasers; also, to investigate patents with respect to validity and practical utility, and give advice upon electrical matters generally. The company has engaged the services of several prominent experts in electrical and mechanical matters as consulting engineers.

The following instruments have been added to the laboratory equipment recently:—a very sensitive reflecting galvanometer, by Carpentier; a milliampere balance of Sir William Thomson's form, by J. White; a reflecting galvanometer of the Hartmann form, designed by Mr. Puffer.

Through the courtesy of the Electrical Club, of Harvard College, the members of the Technology Electric Club were invited to listen to a lecture given at the Jefferson Laboratory, December 2, by Professor Trowbridge upon "The Nature of Electricity."

After two years of publication the *Technology Quarterly* has ceased to exist. This journal, designed as the exponent of the scientific work of the school, deserved a better fate, after the earnest work of the under-graduate editors and the active interest of the professors. Lack of financial support was the cause of the discontinuance of the journal.

Mr. Stephens, instructor in mechanical engineering, has resigned after seven years of service. He will be succeeded by Mr. Miller, '86, now instructor in the mechanical engineering laboratory. Mr. C. A. French, of the department of mathematics, has also resigned.

Twenty-seven members of the Technology Electric Club dined Friday, December 13, at Young's Hotel After dinner President Carlisle announced from the head of the table the object of the business meeting and presented Mr. G. E. Hale, '90, who opened a discussion upon the establishment of the club upon a permanent basis. Following Mr. Hale, various members of the club expressed their views. The general sentiment was averse to any action at the present time.

POINTERS.

.... INSURANCE companies are suspicious of electric light plants and electric wires, and are inclined to base high rates of premiums on their fears. It is good economy to show by results that the underwriters are mistaken.—*C. C. Haskins.*

.... IT is sometimes forgotten that it is almost never the solver of a difficult problem, but really the propounder of the problem, who is an inventor.—*John Perry.*

.... THE electric motor driven from a current produced by water power is as near the fountain head of natural energy as is the steam engine.—*R. W. Pope.*

.... THE progress of science is not so much that of an army as a crowd of searchers, and that a call in the false direction may be responded to, not by one only, but by the whole body.—*S. P. Langley.*

.... SAFETY and danger are terms which have not an absolute, but only a relative, meaning. To permit the wholesale introduction of overhead wires by an unlimited number of companies, good, bad and indifferent, throughout London, would certainly be extremely unsafe; but to permit a few responsible companies, accustomed to good work, to put up a limited amount of overhead wires need not necessarily involve any great danger to the public.—*Industries.*

.... A KNOWLEDGE of what is meant by amperes, volts, ohms and watts, cannot be obtained merely by listening to lectures or by reading. Just as a little use of a watch, of a two-foot rule, and of a spring-balance give exact practical notions of the measurement of time, of distance and of force, so the use of an ammeter and voltmeter will give exact practical notions about Ohm's law and electric measurements generally.—*John Perry.*

.... IN every direction the interests of the public are being criminally neglected through the ignorance of public authorities, and the blindness of their constituents. Property and energy representing millions upon millions of dollars are wasted yearly, which might be saved by heeding the advice of trained engineers. —*R. W. Pope.*

.... IF there is any one thing in the whole business of electric lighting for which I have the most thorough and uncompromising dislike for testing circuits, it is the magneto-bell.—*C. C. Haskins.*

.... THE great majority, even of the students of science, must take their opinions ready-made as to science in general; each knowing, so far as he can be said to know anything at first hand; only that little corner which research has made specially his own. —*S. P. Langley.*

OBITUARY.

E. N. Dickerson.

The death of Mr. E. N. Dickerson, which occurred at Far Rockaway, December 12, leaves a void in electrical circles second only to that caused in the legal profession. Devoting himself at an early period of his career to the practice of patent law, he soon acquired marked distinction in that branch of his profession; a distinction largely due to his scientific and technical knowledge, acquisitions which, united with his unusual faculty of insight and discrimination, and supplementing his legal training, qualified him to take a leading part in legal contests over patented inventions. The science and the arts of electricity attracted his attention and interest in an eminent degree, and it is mainly through the prominent part that fell to him in much of the most important electrical patent litigation of recent years that Mr. Dickerson became so well known and so highly valued by electrical inventors and engineers.

E. N. Dickerson was the son of Philemon Dickerson, Governor of New Jersey in 1836, and was a nephew of Mahlon Dickerson, also governor of that state, and sometime secretary of the navy. He was graduated from Princeton College when but eighteen years old, and three years later was admitted to the bar. After a few years he gave up practice for a time to devote himself to scientific studies and foreign travel. Upon his return he took up his law practice in this city, and started forth in his brilliant course as a patent lawyer.

Mr. Dickerson was a man of striking figure, being much over six feet in height and of robust appearance. Like most big men he was genial and warm-hearted. He not only gave sympathy but expected it. A noticeable trait in his character was his habitual reaching out to others for intellectual appreciation of his work for the time being and participation in his absorbing interest in it. The strong and witty things he did and said were many. He was an artist in denunciation, and scarcely less so in encomium.

Mr. Dickerson has recently been directly interested in electrical industry, having become the President of the "C. & C." Electric Motor Company, of this city.

He was a vice-president of the New York Electric Club. At a meeting of the Board of Managers, held December 19, the following resolutions were adopted :—

> *Resolved*, That in the death of Vice-President E. N. Dickerson the Electric Club loses a valued and highly esteemed officer, a gentleman of great ability, scientific attainment and vast general information, and whose kindly nature made him the friend of everyone and everyone his friend who had the pleasure of his acquaintance.
>
> *Resolved*, That this resolution be spread upon the minutes of the Club, and a copy of the same be suitably engrossed and forwarded to the family of the deceased, and also that copies be furnished to the principal electrical and scientific papers.

Mr. Dickerson left a widow and one son, Edward N. Dickerson, Jr., who has been his law partner. The United States Courts in this city adjourned on December 12 when his death was announced, as a mark of respect for his memory.

Miles W. Goodyear.

Mr. Miles W. Goodyear, who had been in poor health for a long time, died suddenly December 15. A disorder of the heart is thought to have been the cause of his death. It would not be easy to point to a figure better known in electrical trade circles than that of Mr. Goodyear. For some twenty years he had been the manager of the electrical department of L. G. Tillotson & Co., and their successors, The E. S. Greeley & Co. Aside from his business qualifications his geniality, affability and good fellowship had made him a host of friends, who will feel a marked personal loss in his untimely death at the age of fifty years.

At a meeting of the Board of Managers of the Electrical Club, of which Mr. Goodyear had been a member since the organization of the club, December 19, resolutions were voted as follows :—

> *Resolved*, That in the death of Miles W. Goodyear this Board has lost one of its most earnest, intelligent and popular co-workers; one who has ever labored enthusiastically for the best interests of the Club which he helped to organize. We found him ever faithful and true, and keenly and deeply regret our loss.
>
> *Resolved*, That this resolution be spread upon the minutes of the Club, and a copy of the same be suitably engrossed and forwarded to the family of the deceased, and also that copies be furnished to the principal electrical and scientific papers.

THE DOWN-TOWN EDISON STATION DESTROYED BY FIRE.

Fire was discovered in the Pearl street station of the Edison Electric Illuminating Co., New York, about half-past six o'clock in the morning, January 2, and spread with such rapidity that the interior of the buildings and the entire apparatus of the station were destroyed within an hour. The station occupied two old buildings, Nos. 255 and 257 Pearl street, and was the earliest central station of importance in the world for the distribution of incandescent electric light over a considerable area. It was the only one of the several Edison stations in this city not housed in a fire-proof structure. It is particularly unfortunate that its destruction should occur after seven years' continuous service—and while the Edison Electric Illuminating Co. were perfecting plans for rebuilding and fire-proofing the premises during the ensuing spring.

The station was equipped with eight of the huge Edison dynamos, and supplied current for 18,000 to 20,000 lamps in the down-town district, bounded roughly by Spruce street, the East River, Beaver street and Broadway. For a few hours there was a total cessation of service, but through the energetic action of the company a partial service was established from the auxiliary station in Liberty street, about eleven o'clock, and by four o'clock in the afternoon a very considerable portion of the district was supplied from that partially equipped station.

Vice-president and general manager John I. Beggs, was promptly on the ground, directing the removal of the debris, ordering the immediate shipment of new dynamos from the machine works at Schenectady, and planning for a temporary equipment to be set up immediately in the lower part of the ruined buildings as soon as the wreckage can be cleared away. Two dynamos were on the way to New York before nightfall, and Mr. Beggs expressed his confident expectation of resuming full service within three days.

The station buildings were owned by the Edison Electric Illuminating Co. Mr. Beggs estimates the company's direct loss by the fire at $30,000 to $50,000 on the buildings, and $100,000 on the station equipment and supplies. The company holds insurance of $30,000 on the buildings and of $81,500 on machinery and stock.

The installation of the Pearl street station was completed in the autumn of 1882. The machinery was started for the first time on the afternoon of September 4, supplying 85 buildings wired for 2,323 lamps. In April, 1884, the service had grown to 500 buildings and 11,272 lamps. The plant has not been idle a day or night since it began operation.

The fire was discovered in the dynamo room. Its cause is still a matter of conjecture.

THE TELEPHONE.

On the 3d of December, before Judge Taft, of the Ohio Supreme Court, the Cincinnati and Suburban Telegraph and Telephone Association began suit for an injunction against the Mt. Auburn Electric Railway Co. to restrain that company from operating its cars by the single trolley lines now in use, because of its injurious effects upon the telephone service. The case is a distinct attack upon the single trolley method of electric railway operation, and its result will be looked for with much interest in telephone and street railway circles.

The hearing of testimony was concluded on the 18th of December, and the arguments of the counsel on both sides occupied two days, the 20th and 21st. The long documents, manuscripts and the testimony in the case were then given to Judge Taft, whose decision is not yet announced.

Foreign.

France.—From Paris despatches it appears that the government has issued new regulations for improving the telephone service recently taken over by the state. A new scale of charges has been arranged as follows :—For the use of a post-office telephone cabin in Paris, 10 cents for every five minutes; elsewhere, 5 cents. The use of a telephone line between two towns is to be charged for at the rate of 15 cents for every hundred miles for five minutes' service. Persons having telephones at their houses may use the long-distance lines at the same rates. No alteration is made in the charge for telephone messages between Paris on the one hand and Brussels, Lyons and Marseilles on the other, which remain at 60 cents, 40 cents and 60 cents respectively. Villages where no telegraph office exists may erect a telephone line at their expense connecting them with the nearest telegraph office, and send and receive telegrams without extra charge.

Austria-Hungary.—The opening of the new telephone line between Buda Pesth and Prague led to so much disputing as to the language which should be used by the employés that it has been decided to use French. By this means alone could the rival claims of Czechs and Magyars, Germans and Poles be satisfied.

Austria.—What is said to be the longest telephone circuit on the continent of Europe, was opened to the public on the 20th of October. The line is from Vienna, in Austria, to Leipsic, and every word could be perfectly understood and the voice recognized without difficulty. The distance between the two cities by rail is something less than 300 miles, but the telephone wires are strung along the highways, and the actual distance on these routes is near 350 miles.

PERSONAL MENTION.

Mr. Carl Hering was handsomely entertained at a banquet given in his honor at the Café Robinet, Boulevard Montparnasse, soon after the close of the Paris Exposition. He was invited to meet some of the leading and most distinguished electricians of

Paris, on this occasion, as was most fitting and appropriate. The Café Robinet is the head-quarters of the electrical society "de la Planché."

Amongst the guests were such men of note as Potier, Napoli, Richniewski, Avizard, Serpollet, Abdank-Abakanowicz and Soulages, no fewer than 11 nationalities being represented and meeting to do honor to Mr. Hering. Among our own countrymen were Messrs. Meech, Thurnauer and Bishop, representing important electrical interests in the United States. The proceedings and speeches were of a high order, and the guests separated at a late hour, with evident appreciation of the elegant hospitality of the French *savants* to their professional brethren.

Mr. J. H. Longstreet, for several years engaged in the manufacture of electrical instruments in this city, has recently purchased the Riverview Iron Works, at Bordentown, N. J., where he has opened business in foundry work, machinery, etc. For a few years past he has been devoting his attention to agriculture.

Mr. E. T. Gilliland, president of the Electric Club, of New York, who is compelled by ill-health to seek a southern climate for the winter, tendered his resignation, in a letter expressing his deep interest in the club and its future work, and enclosing a pledge of substantial financial aid.

At a meeting of the board of managers of the club, held December 19, the following resolutions were unanimously adopted :—

> *Resolved* :—1st. That we learn with extreme regret of the illness of our honored president, and while accepting the resignation which his illness compels, we desire to testify to our appreciation of his earnest work in behalf of the club, and to express our thanks for the substantial subscription which accompanies his letter of resignation, and which is only one of many favors the club has received from him. We sincerely hope for his early restoration to health.
>
> 2d. That, desiring not to lose Mr. Gilliland's valuable assistance on this board, should he be able to meet with us on his return from the south, we unanimously ask him to remain as vice-president of the club.

At the same meeting, Mr. O. E. Madden was unanimously elected president of the club, to fill the unexpired term.

Mr. Ira Cornwall, Secretary of the St. John, N. B. Electrical Exhibition Committee, on December 21st, received from the committee a highly complimentary letter, accompanied by a gift, consisting of an elegant clock and bronze ornaments, the whole expressive of the committee's appreciation of the energetic and successful planning and conduct of the recent exhibition, which was so largely due to Mr. Cornwall's gratuitous services.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

Programme for the Convention at Kansas City, February 11-14.

Mayor Davenport will welcome the Association and attending visitors to Kansas City.

President E. R. Weeks will open the Convention with a brief address.

Secretary and Treasurer Allan V. Garratt will make the usual reports.

PAPERS.

Professor Elihu Thomson. "Safety Devices in Electrical Installations."

Professor Henry A. Rowland.

Professor Rowland has kindly consented to prepare a paper based upon a correspondence with the members of the Association by the Secretary, for the purpose of ascertaining the technical questions with which they find the greatest difficulty.

Mr. Thomas A. Edison will give an address—the subject of which is not yet announced—by phonograph, which will reproduce Mr. Edison's voice loud enough to be heard in all parts of the house. As but few persons have ever heard Mr. Edison speak in public, this address from the phonograph will be of unusual interest.

Mr. Frank J. Sprague. Subject: "Electricity as Applied to Street Railways."

Mr. F. E. Sickels. Subject: "The History and Theory of the Steam Engine."

Mr. George H. Babcock. Subject: "The Economic Generation of Steam."

Mr. Myron D. Law. Subject: "Nine Years with the Arc Lamp."

Mr. C. A. Harber. Subject: "Line Insulation from the Standpoint of Practical Experience."

Mr. T. Carpenter Smith. Subject: "A Universal System of Central Station Accounts."

Mr. A. J. De Camp. Subject: "The Cost of the Products of Central Stations."

Mr. C. J. H. Woodbury. Subject: "Central Station Construction."

Mr. C. J. Field. Subject: "A Recent Edison Central Station and the Results thus far Obtained."

Mr. Henry W. Pope. Subject: "How Our Paths May Be Paths of Peace."

Mr. C. C. Haskins. Subject: "Prodigality in Economy."

Mr. E. F. Peck, in the discussion of Mr. M. L. Law's paper, will give the results of his numerous tests of arc light carbons.

Papers from several other prominent gentlemen are looked for, and will be announced later.

REPORTS WILL BE MADE BY

The Executive Committee, Mr. G. W. Hart, chairman.

Committee on Patent Legislation, Mr. Arthur Steuart, chairman.

Committee on Underground Conduits and Conductors, E. T. Lynch, Jr., chairman.

Committee on Harmonizing Electric Light and Insurance Interests, Mr. P. H. Alexander, chairman.

Committee to Confer with Mayor Grant in regard to the International Exposition of 1892, Dr. Otto A. Moses, chairman.

Committee on Electrical Data, Mr. A. R. Foote, chairman.

Committee to Memorialize Congress on the Abolition of Custom Duty on Copper, Mr. C. A. Brown, chairman.

Committee on Electrical Execution, Mr. E. W. Maher, chairman.

Committee on Standardization of Potential on Electric Street Railways, Mr. E. T. Lynch, Jr., chairman.

National Committee on State and Municipal Legislation, Mr. A. R. Foote, chairman.

ELECTRIC LIGHT AND POWER.

Mr. Orlo V. Thomas, electrician-in-charge of the electric light station at Taunton, England, communicates the following to the *Electrician* (London), November 23d, 1889:—

"It may interest you to know that an incandescent lamp (Woodhouse & Rawson), which was put up on September 22d, 1888, and which has been burning continuously ever since, has now burned out, after the phenomenal life of 10,608 hours. As this was a 98-volt lamp, and was on the charging leads of a 50-cell battery, you will see that during a considerable part of its life it was burning a good deal above its nominal candle-power."

The Louisville Electric Light and Power Co., New Orleans, La., has changed its title to the Louisiana Electric Light Co., and will increase the capacity of its plant from 2,000 arc and 6,500 incandescent lights to 4,000 arc and 40,000 incandescent. The Fort Wayne Jenney Electric Light Co., of Fort Wayne, Ind., will furnish the machinery.

The Easton Electric Co., of 45 Broadway, New York, has concluded a contract with the city of Rockland, Me., by the terms of which the company is to light the streets of that city for a period of five years. The Easton company has recently been reorganized. Its officers are :—President, P. Minturn Smith; vice-president, Wm. D. Perry; secretary, G. G. Frelinghuysen; treasurer, Charles Tremaine; electrician, James W. Easton. The management goes to work energetically, and invites investigation into its system. The electrician of the company, Mr. Easton, is well known in electric light circles through his inventions in that art.

The Heisler Electric Light Co., of St. Louis, announce that after mature deliberation they have decided to change their standard lamps from 30 to 32 c. p., and from 15 to 16 c. p., thus falling in line with other manufacturers in this respect. They have found themselves sometimes at a disadvantage where specifications stipulate the 16 and 32 c. p. lamps. They adhere, however, to their faith in the larger lamps, and will use the 32 c. p. lamp as their standard.

Wabash, Ind., was among the first cities to adopt the plan of lighting by arc lights on towers. This plan was subsequently displaced by the Heisler incandescent system, and the lights distributed through the streets of the city. For some time this plant was operated solely for public lighting, but a demand having sprung up for incandescent lights for commercial and domestic lighting, the company decided to make considerable enlargements, and placed their order with the Heisler Electric Light Co., of St. Louis, for one of their latest improved dynamos, having a capacity of 350 32 c. p. lights.

The La Grande Edison Electric Light Co., Oregon, has been organized. President, W. H. McDonald; vice-president, H. Ansen; manager, J. K. Roming. The plant will have a capacity of 800 16 c. p. Edison incandescent lamps. The station plant will consist of two Edison dynamos, driven by a 50 h. p. Ball automatic engine, with a 60 h. p. horizontal tubular boiler, made by the Ball Manufacturing Co.

Supt. J. E. Powell has made the following recommendations, which have been approved by the Secretary of the Treasury:—"It should be stated that the qualifications of persons to fill the position of chief engineer of the public buildings containing large electric lighting plants should be carefully inquired into, particularly in regard to their knowledge of electric lighting. The ordinary examination required from United States Local Inspectors of Steam Vessels, while it may protect the department from employing men incompetent as engineers, does not and cannot protect it from incompetent electricians and secure it the service of men skilled both as engineers and practiced in the management of electric lighting plants. I recommend that applicants for the positions of chief engineer and assistant engineer in public buildings, having electric lighting plants owned by this department, be required to present satisfactory evidence of their ability to operate electric lighting plants in addition to the requirements ordinarily exacted of the engineers."

Foreign.

Mexico.—Mr. Theo. Plate, president of the Interstate Gas & Water Works Co., of St. Louis, has recently secured franchises extending over long terms of years, for erecting and operating incandescent electric light plants in the cities of Durango and Aques Calientes, Old Mexico. In both cases the franchises are accompanied with contracts for lighting the streets and other public places. In Durango, the authorities use 200 32 c. p. lights and 150 16 c. p. lights, and at Aques Calientes, 150 32 c. p. lights and 175 16 c. p. lights. These lights are to be operated about 240 hours per month. The Heisler system of long-distance incandescent lighting has been adopted for these plants, and orders have been placed with the St. Louis office of the company for complete outfits of central station apparatus. The plants will be models in every way, and on account of the high cost of fuel, compound condensing engines of the high speed type will be used. It is expected that this apparatus will be ready for shipment in January, as the plants are to be in operation in time for the annual festivals, which take place early in the spring. Mr. Plate and his engineer, Mr. Andrews, left for Mexico on the evening of the 21st of December, to begin active operations.

MANUFACTURING AND TRADE NOTES.

The Wainwright M'f'g. Co., of 34 Oliver St., Boston, Mass., have recently furnished the following electrical plants with their corrugated copper tube feed water heaters:—Canada Electric Co., Nova Scotia, 100 h. p.; Edison Electric Light Co., Penn., 300 h. p.; No. Attleboro Steam and Electric Co., Mass., 250 h. p.; Marr Construction Co., Mass., 150 h. p.; Lewiston Electric Light and Heat Co., Ill., 75 h. p.; Belfast Electric Light Co., Maine, 100 h. p.; Denver Tramway Co., Col., 400 h. p.; Greensburg Electric Light Co., Ind., 100 h. p. The Wainwright company report business rushing in heaters, condensers, expansion joints and separators.

Messrs. J. H. Bunnell & Co., of New York, so long and well known as an electrical manufacturing and supply house, have removed to Cortlandt and Washington streets. The distance is short from their old quarters in Liberty street, and the new location is conveniently near the offices of the large number of electrical interests in upper Cortlandt street.

Messrs. Ames, Crerar & Co., northwestern agents of the Western Electric Co., have opened a general supply store for electrical goods at 51 East 4th street, St. Paul, Minn. They will keep in stock a full line of electrical supplies including insulated wires, linemen's tools, switches, cut-outs, incandescent lamps, electric bells and annunciators, batteries, etc.

They will also give attention to construction work, and will have a competent force of men to undertake all kinds of electrical contracts such as central station and isolated electric light plants, fire alarm and call bell systems, etc.

Mr. B. L. Ames, who will have personal supervision of the business of the concern, is a graduate of the Massachusetts Institute of Technology, and has had several years experience as manager of successful electric light plants, both arc and incandescent.

The Sawyer-Man Electric Co. has been given the contract for supplying lamps to the Boston post-office. It is stated that the new contract is based upon a higher price for lamps than has been paid by the post-office for lamps of other manufacture under a former contract.

The Westinghouse Electric Co.'s returns of orders for December, up to the 15th, indicate the safe assumption that as far as business is concerned, the month will prove a fitting climax of a very successful year. Among other contracts, the company obtained an order from St. Louis, Mo., for alternating current apparatus of a generating capacity of 3,000 lights; a similar order was also secured from the local company in Denver, Colorado, and a third and larger one from Portland, Ore., for 6,000 lights and 100 arc lights. The specifications of the latter contract called for special machinery of 4,000 volts. The plant is to be run by water power, which is 12 miles away from the scene of the distribution of the electric current.

The total amount of apparatus disposed of by the company during the year 1889, will aggregate a capacity of at least 250,000 lights. This figure may be better understood from the following comparison:—The company was organized in the latter part of 1886, and during the period previous to the beginning of 1887, apparatus for central station plants of a capacity of 2,400 lights was disposed of. During the year 1887, the total sale of machinery represented a capacity of 106,200 lights, and during 1888 the aggregate amount of apparatus sold footed up a total capacity of 119,950 lights.

From these figures, it is readily discernible that the business of 1889, will not only more than double the amount of business of either of the two previous years, but it even exceeds the total amount of sales made from the day of the company's organization until the beginning of the year 1889.

This record of three years is gratifying, as indicating the accelerating pace of electrical industry generally, and particularly so to the Westinghouse Electric Co. in the extraordinary rise and growth of its business.

The Willamette Falls Electric Co., of Portland, Ore., has made a contract with the Westinghouse Electric Co., of Pittsburgh, Pa., to furnish them with machinery for the establishment of a central station plant of 6,000 incandescent lights and 100 arc lamps, to light up the city. The plant will be situated at Willamette Falls, about 12 miles from the city, where the electric current is to be generated by water power. The company has ordered the Westinghouse people to make special machinery for this contract to produce a current of 4,000 volts. There will be a branch central station in the city, from which the current will be distributed. Only one arc light machine will be used for the 100 lamps, this being a dynamo of the new arc light system recently brought out by the Westinghouse Electric Co.

The Thomson-Houston Electric Co. report the following sales with the number of lights in each case.

Incandescent apparatus to central stations:—

Sioux Falls, So. Dakota, 50; Tuscumbia, Ala., 100; May's Landing, N. Y., 400; Portland, Me., 800; St. John. Mich., 500; Boston, Mass., 500; Adams, Mass., 500; Middlesboro, Ky., 300; Seymour, Conn., 500; Langhorn, Pa., 500; Plymouth, Mass., 500; E. Greenwich, R. I., 850; Oswego, N. Y., 1,300; Hyde Park, Mass., 1,300; Andover, Mass., 650; Winchester, Md., 650; Somerset, Ky., 650; Watertown, N. Y., 650; Catskill, N. Y., 650; Rochester, N. Y., 650; Huntington, Pa., 650.

Arc apparatus for central stations:—

Lowell, Mass., 25; Rochester, Md., 50: St. John, Mich., 30; Camden, Ark., 30; City of Chicago, Ill., 210: Chicago, Ill., 100; Litchfield, Ill., 50; Fairhaven, Wash., 30; Chattanooga, Tenn., 100; Toledo, O., 50; W. Superior, Wis., 50; Cincinnati, O., 200; Macon, Ga., 100; Pottstown, Pa., 50; Spokane Falls, Wash., 100; Huntington, Pa., 50; Bedford, Me., 50; Long Branch, N. Y., 100; Wilkesbarre, Pa, 50; Austin, Minn., 50; Weymouth, Mass., 60; New Haven, Conn., 50; Missoula, Mont., 50; Sedalia, Mo., 100.

Arc apparatus for isolated plants:—

Allentown Rolling Mill, Allentown, Pa., 18; L. F. Bartlett, E. Saginaw, Mich., 18; Pioneer Mining and Manufacturing Co., Thomas, Ala., 37; Merrimac Man. Co., Lowell, Mass., 45; G. F. Blake Man. Co., E. Cambridge, Mass., 30.

Incandescent apparatus for isolated plants:—

E. A. Gyde, E. Saginaw, Mich., 35; National Transit Co., Kane, Pa., 100; National Transit Co., Parker Landing, 100; Water Works building, Detroit, Mich., 100; St. Clair Hotel, Cincinnati, O., 100; Louisville Chair Co., Louisville, Ky., 200; J. O. Shoup & Co., Dayton, O., 1,600; Norfolk Woolen Co., Norfolk, Mass., 50; Wadsworth Howland & Co., Malden Mass., 50; J. W. Ayer, Brewer Village, Me., 50; Allentown Rolling Mill, Allentown, Pa., 200; White Cycle Co., Westboro, Mass., 100; Midgeley Wire Belt Co., Beaver Falls, Pa., 100; Locke Bros., Salem. Mass., 200; Woodrough & McFarlan, Cincinnati, O., 200; H. A. Marston, So. Framingham, Mass., 200; Eastern Manufacturing Co., Brewer, Me, 200.

The Westinghouse Machine Co. reported that "high-water mark" had been reached in that company's business during the month of October, 1889, the sales being the largest in the company's history up to that time, and amounting in the aggregate, including Junior, Standard Westinghouse and Compound engines, to 6,035 h. p. The month of November, 1889, however, shows even better results, with the following:—

34 Junior engines	940 h. p.
31 Standard engines	940 "
39 Compound engines	5,300 "
104 engines, aggregating	7,180 h. p.

The sales of both months are in excess of the company's producing capacity, notwithstanding the heavy additions recently made to their machinery, and the puting on of a night force. It is hoped and believed that orders will slacken up during the winter, so that the company may thus be enabled to restore the sadly depleted stock of finished engines in its warehouse.

The Sawyer-Man Co.'s factory, 510–534 West 23d street, is still overrun with orders for incandescent lamps, and although running night and day finds it impossible to keep up with the demand, being about 100,000 lamps behind their orders. Extensive additions are being made to the plant, and when completed there will be nearly 900 exhausting pumps in use.

The Crocker & Wheeler constant current electric motors are meeting with marked success for use on arc-lighting circuits and constant current power circuits. A recent order from London for twenty of these motors is significant of their appreciation in England. The motors are manufactured by the Crocker-Wheeler Electric Motor Co. The Sprague Electric Railway and Motor Co. are sole agents for their sale.

The Calumet & Michigan Telegraph Co. has been formed at Chicago, to construct and maintain a line for the transmission of all kinds of electric signals. Capital stock, $500; incorporators, Wallace Fairbank, Spencer Eddy and G. M. Glessner.

The Knapp Electrical Works, of Chicago, certificate of incorporation was issued in November. The capital stock is $100,000, and the incorporators are F. M. Knapp, M. A. Knapp and L. K. Bryeson. This establishment was formerly known as the Railway Telegraph Supply Co.

The Park Ridge Arc Light & Power Co. has been organized at Chicago, with a capital stock of $50,000. The incorporators are F. B. Clark, M. T. Cahill and Edward Slack.

ELECTRIC STREET RAILWAYS.

The Thomson-Houston Electric Co. report the following new railway contracts:—

Brooklyn, N. Y., Coney Island & Brooklyn Railroad, 16 miles; 25 motor cars.

Salem, O., Salem, City Street Railway Co., 2 miles; 3 motor cars.

Utica, N. Y., Utica Belt Line Railway, 20 miles; 25 motor cars.

The Sprague Electric Railway and Motor Co. report new railway contracts as follows:—

Kearney, Neb., 8 miles; 2 motor cars.

Denver, Col., Colfax Avenue Electric Railway, 4 miles; 4 motor cars.

Salem, O., Capital City Railway, 3 miles; 2 cars.

Sprague roads reported as constructing December 1, 1889, have since been put in operation as follows:—

Cleveland, O., Broadway and Newburgh Street Railway, 10 miles; 16 cars. Detroit, Mich., Detroit, Rouge River & Dearborn R. R., 1 mile; 1 car. Moline, Ill., Moline Street R. R., 2 miles; 2 cars. Plattsmouth, Neb., Plattsmouth Electric R. R., 2 miles; 2 cars. Portland, Ore., Willamette Bridge & Ry. Co., 1.5 miles; 5 cars. Sterling, Ill., Union Elect. R. R., 6 miles; 7 cars. Wilkesbarre, Pa., Wilkesbarre and West Side R. R., 4 miles; 3 cars. West Bay City, Mich., West Bay City Elect. Ry. Co., 5 miles; 8 cars.

Thomson-Houston roads under construction November 15, 1889, were put in operation before December 15, as follows:—

St. Paul, Minn., St. Paul & Minneapolis Ry. Co., 20 miles; 20 cars. St. Louis, Mo., St. Louis Bridge Co., 2 miles; 4 cars.

The Short Electric Railway Co. reports the following contracts:—

S. Covington and Cincinnati Street Railway Co., Madison street and Main street lines, 8 miles; 10 motor cars.

Muskegon, Mich., Muskegon Electric Railway, 4½ miles; 5 motor cars.

The Columbus Consolidated Street Railway Co. has contracted with the Short Electric Railway Co. for the track wiring for the parallel systems of electric traction.

Pittsburgh, Pa., Pittsburgh Traction Co., 2 miles; 10 motor cars; short parallel system.

Cincinnati, O., S. Covington and Cincinnati Street Railway Co., 8 miles; 10 motor cars; short double wire parallel system.

The Van Gestel Electric Street Car Company, New York, in a circular dated December, 1889, announces its readiness to give estimates for equipping railroads, lighting towns, or for individual plants, with catalogue, giving full descriptions, cuts and plans of the entire system. From the circular it would appear that the "system" of "electro-motion" consists in the use of a separate locomotive equipped with storage batteries. At any rate no peculiar apparatus, methods or details are set forth.

Salem, O.—The Electric Street Railway is under construction and making rapid progress. The road is two miles long and will be equipped with the Thomson-Houston system. Three motor cars are ordered.

LEGAL NOTES.

THE EDISON LAMP PATENT IN CANADA—IT IS DECLARED VALID.

Reversal of the Judgment of the Deputy Commissioner of Patents.

Before the Hon. John Carling, Minister of Agriculture.

The Royal Electric Company of Canada, *Petitioners*, and Edison Electric Light Company, *Respondents*.

Messrs. Z. A. Lash, Q. C., of Toronto, R. D. McGibbon, of Montreal, Curtis, of New York, and Kerr, of Pittsburgh, Pa., counsel for petitioners.

Messrs. Hector Cameron, Q. C., B. B. Osler, Q. C., of Toronto, McMaster, Q. C., of Montreal, and Grosvenor P. Lowrey, of New York, counsel for respondents.

This is a re-hearing of the case, on the petition of the Royal Electric Light Co., of Canada, tried before Mr. Richard Pope, the Deputy Commissioner of Patents, and on which he gave a decision, on the 26th February last, annulling the Edison patent, in virtue of sec. 37, chap. 61, Revised Statutes of Canada. [See Electrical Engineer, April, 1889, page 199.]

A doubt having arisen as to the jurisdiction of the Deputy Commissioner of Patents, in virtue of the provisions of the section of the act referred to, it was decided that the case should be commenced *de novo*.

A re-hearing accordingly took place before me on the 23d July last.

The evidence taken at the previous hearing, before the Deputy Commissioner of Patents, was accepted by both the petitioners and the respondents, and some additional evidence was taken. The counsel on both sides argued the question at issue, from their respective standpoints, with great clearness and ability.

In addition to the arguments at the last hearing, Mr. Lowrey, on behalf of the respondents, with consent, put in a written statement of argument, a copy of which was communicated to Mr. Lash, and to which he subsequently furnished a reply.

After a careful consideration of the evidence I decide as follows:—

(1) I find that Thomas Alva Edison, the patentee of the patent in the proceedings mentioned, did, within two years from the date of such patent, commence, and, after such commencement, did continuously carry on in Canada the construction and manufacture of the invention patented, in such manner that any person desiring to use it might obtain it, or cause it to be made for him, at a reasonable price, at some manufactory or establishment for making or constructing it in Canada.

(2) I further find that, after the expiration of 12 months from the granting of the said patent, neither the said patentee nor any person claiming or holding under him did import or cause to be imported into Canada the invention for which the said patent was granted.

I do, therefore, in pursuance of the statute in that behalf, declare that the said patent has not become null or void, and I dismiss the application of the petitioners, the Royal Electric Co., of Canada. John Carling, *Minister of Agriculture.*

Department of Agriculture,
Ottawa, 25th November, 1889.

The Hon. Sir John Thompson, Minister of Justice, sat with the Minister of Agriculture at the hearing. The following are extracts from his report on the case, dated Ottawa, 30th October, 1889, and addressed to the Minister of Agriculture:—

The nature of the petition, and of the various proceedings taken under it, down to the time when it was heard by Mr. Richard Pope, Deputy Commissioner of Patents, are recited in the decision which was rendered in this case on the 26th of February last by that gentleman. [See Electrical Engineer, April 1889, page 199.] I need not detail these matters again, because the narration by Mr. Pope indicates them sufficiently, although it will be seen that I do not concur in his conclusions as to what was established by the evidence, in regard to many important points, but arrive at conclusions almost directly opposite. In order that the explanation of the fact that the case subsequently came before us may appear in the record, I may remind you that after the decision of Mr. Pope was pronounced the respondents made application to the Governor General in Council, praying, on various grounds, that effect should not be given to that decision. The application was then referred to you and myself by His Excellency in Council, for report, and on the examination of the subject which ensued it seemed to be at least, doubtful that Mr. Pope, as Deputy Commissioner of Patents, possessed the necessary jurisdiction to hear and decide on such a petition, or to pronounce judgment upon it.

It was, accordingly, deemed best that the whole matter should be re-heard before yourself as Minister of Agriculture; and you having desired my assistance at the hearing, I had the pleasure of hearing this most important subject very ably discussed. It was agreed at that time (subject to certain reservations which are not important now), that all the evidence, proceedings and arguments which had taken place before Mr. Pope should be considered as re-taken before yourself, and should be used to the same extent as if you had heard them. This evidence, and the report of the arguments which had taken place before Mr. Pope, together with the arguments which we heard, and the briefs which were subsequently handed to us, contain the material on which I am now to give you my opinion.

* * * * * * * * * *

The application of the petitioners, rests on the set of facts following:—

The patentee has made his lamps out of glass bulbs and glass tubes made in the United States and imported from there into Canada; with platinum wires produced from platinum, mined in Russia, manufactured into wire in the United States and imported into Canada from there; with filaments of bamboo, grown in Japan, imported thence to the United States, carbonized partially in furnaces there, and imported thence into Canada, with brass bottoms made in the United States, to fit into lamp sockets, and imported into Canada; also with copper wire which has come from the United States.

The glass bulbs and tubes are the first articles to be considered. It is admitted that they are articles of commerce in the United States, in Canada, and in almost every other country, and were so for many years before the patent.

It is clear that bulbs and tubes of that description are used for other purposes than for electric lamps, the bulb being the simplest form the glass takes in the process of blowing, and the tubing being made and used for a great variety of purposes.

* * * * * * * * * *

A description of the patented lamp does not mention the glass bulb as being an essential part of the lamp. A transparent chamber of any shape, or of several parts joined, capable of affording a vacuum, would suffice. Therefore, the bulbs and tubes are not used exclusively for this purpose and are not even essential to the invention, strictly speaking.

These bulbs and tubes, as I have said, are not a part of the claim in the patent. In fact, it is quite possible to conceive of the patented article being made without them—made, for instance, in some other shape. However this may be, they are articles of commerce, which any one may import, manufacture, sell or use without infringing the patent. They were in use long before electric lamps were invented, are used for other kinds of electric lamps, and I cannot come to the conclusion that the importation of these into Canada incurred the forfeiture of the patent.

What I say on this point may be taken as said of many other articles which go into the composition of the lamp, and which will be referred to hereafter.

It does not seem reasonable that a person who has been placed expressly under the protection of the patent law, as a reward for inventive genius, and for expenditure of labor and capital in devising a patented article, should be subjected to enormous penalties for doing what everybody else may do, and I do not think that such would be a correct construction of the law.

It is clear, to my mind, that in respect of all these articles [glass bulbs, platinum and copper wires, etc.,] (and only one remains to be considered), every one of them is of the public domain, free to every person in Canada to manufacture, import, sell and use without thereby infringing the patent under consideration, and that, in respect of their use, the respondents incur no greater liability or penalty than they incur by importing, and not manufacturing, the plaster with which they seal the lamps, or any of the common appliances of the workshop which may be used in the manufacture.

The carbon filament remains to be considered.

This is described in the patent claim as "a filament of carbon of high resistance, made as described, and secured to metallic wires as set forth," etc.

The strips of bamboo, out of which filaments are made, are imported from Japan, are split into threads in the United States, baked into a partly carbonized condition there, and sent from there into Canada. As a matter of fact, it seems that the carbonizing of the filament is a very difficult work, requiring great experience and skill. It has been principally done by Mr. Edison himself, and although perhaps, sometimes done by others has so often failed in the hands of others, even of those who had temporarily succeeded, that the work is practically reserved for Mr. Edison's factory in New Jersey, or was so at the time under consideration.

This was the case as to filaments for use in Europe as well as for use in Canada.

* * * * * * * * * *

After being brought into Canada it is attached to the leading wires and, during the process of exhausting the air from the glass bulb, is subjected to an electric current for the greater portion of half a day. The carbonizing which it receives in the United States and the treatment by electric current after it arrives in Canada, before the final completion of the lamp, are what make the filament a filament of high resistance and fully carbonized. It could hardly be said to be fully carbonized until the treatment which is given in Canada has been applied. * * *

I must observe of the filament, as of the other articles which I have enumerated, that the production or manufacture of this article is not covered by the patent claim or by the patent. True, it is a most essential part of the patented invention. It may, perhaps, be said to be what Mr. Pope declares it to be, "the novelty which the inventor has contributed to the art of incandescent lighting." To my mind, however, there is a mistake, which would lead to an erroneous conclusion on the whole subject, involved in the proposition which has been put before us in the following words:—"The carbon filament, as imported by the patentee and his representatives, the respondents, * * * is claimed in and covered by the patent; * * anyone who should use it, without the permission or consent of the respondents, would render himself liable to them in an action for infringement of the patent." Reading these words in connection with the statement that "the carbon filament of high resistance is the novelty which the inventor contributed to the art of incandescent lighting," one would expect, in turning to the patent, to find a patent simply for "a carbon of high resistance," because nothing but a novelty can be the subject of a patent, unless it be a new combination, and the language used in the proposition before quoted would not apply to a combination. But the carbon filament is not "the invention for which the patent is granted" (to quote the exact words of the enactment prohibiting importation, which is invoked here). On the contrary, the production of the filament is not covered by the patent at all. The "invention for which the patent is granted" is a *lamp* in which the filament is to emit the light. The lamp was old, the filament new. The combination was patented.

* * * * * * * * * *

If the making of a filament of carbon is not patented, but only the construction of a lamp with such a filament, the patentee is bound to manufacture his lamp, with the filament in it, in Canada; but he is not, I think, bound to manufacture his filament here.

* * * * * * * * * *

As I have already intimated, however, inasmuch as the making of the filament is not patented by this patent, I think that the filaments stand in the same position as all the other articles which go to form the lamp.

* * * * * * * * * *

If the parts were ready for use in the construction of the lamp—ready to be assembled, and merely requiring to be assembled in order to produce the patented invention, as seems to have been the case with regard to the Bell Telephone,—we should have to consider the question as to whether the invention for which the patent was granted was not really imported into the country, although imported in parts. We should then have to consider, with much doubt and difficulty, as I have already suggested, whether the penalty provided by the statute should not be attached to that offense to prevent an evasion of the law; but, in my view of the evidence, it is unnecessary to consider the case from that point of view, and it would be improper to decide it on any such principle.

* * * * * * * * * *

After reviewing some of the evidence as to the amount and kind of work done in Canada to produce lamps from the articles imported, the Minister says:—

This seems to show conclusively to my mind (1) that the invention for which the patent was granted was not imported, but was manufactured in Canada, and (2) that the invention for which the patent was granted was not imported *in parts.*

There remains to be considered the charge that the patented article was not manufactured in such a manner that any person who desired to use it could obtain it at a reasonable price. There is much evidence on this point. There is evidence that the respondents, at one time, refused to sell the lamps to persons who did not intend to use them with the Edison plant.

It seems that the Edison plant is simply a description of dynamo which Mr. Edison uses. It is not a machine of which he has the patent or any monopoly. The dynamos which are called the Edison plant can be purchased in Canada and in the United States. The explanation made in the evidence is that the electric lighting business was then in its initiatory stages, and that it was deemed by the Edison company most important that the success of the lamp should not be prejudiced in the public estimation by its being used in connection with plant which they believed it could not be used with successfully.

Under the charge of refusing to sell at a reasonable price, and as to the evidence of a refusal to sell, except for use on the Edison plant, the questions to be determined are:—

Is the evidence to be relied on which declares that this was the only limitation to the sale? and

Was the limitation made in good faith, in order to prevent the success of the lamp being destroyed and to prevent public opinion being prejudiced against it at a critical stage of the electric light business?

Was it reasonable?

Or, was the whole business carried on merely as a sham to avoid the forfeiture of the patent, while the company had no intention of really doing business in Canada?

* * * * * * * * * *

I am inclined to think that the evidence on this point in exoneration of the respondents from the imputation of bad faith, should be accepted. The burden of proof was on the petitioners to make good the charge of bad faith and of refusal to sell; and, in view of the explanations which some of their officers have made on this point, I see no good reason to doubt that the company were manufacturing lamps to sell, and intending to do so in good faith.

I think that the removal of their factory from Montreal to Hamilton, where greater facilities were expected and obtained, the enlargement of their business there, the contracts which the

MISCELLANEOUS.

In the suit of The Electrical Accumulator Co. *vs.* The Gibson Electric Co., in the United States Circuit Court for the Southern District of New York, which was instituted in February last, the complainants recently moved for a preliminary injunction, and Judge Lacombe on Friday, November 29, granted the motion, and the injunction issued. The complainant's testimony is to the effect that the Gibson company has continuously infringed the Faure patent, and that their various modifications are infringements.

At Troy, N. Y., a temporary injunction has been granted to the Hudson River Telephone Co. against the Watervliet Turnpike and Railway Co. The telephone company seeks to restrain the railroad company from operating its cars by the single-trolley electric system. A motion to make the injunction permanent will be argued at a special term.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From November 19 to December 10, 1889 (inclusive).

Alarms and Signals:—*Electric Police Signal System*, C. E. Scribner, 415,574. *Fire Alarm Telegraph Repeater*, F. A. Skelton, 415,578. *Fire Alarm Box*, G. L. Foote, 415,629, November 19. *Thermo-Electric Indicator*, F. W. Wiesebrock and E. Huber, 415,758. *Electrical Annunciator*, C. E. Lee, 415,915, November 26. *Gong or Tap Bell*, J. P. Tirrell, 416,243. *Electric Alarm*, R. D. O. Smith, 416,381. *Auxiliary Fire Alarm System*, T. Cooper, 416,444. *Auxiliary Fire Alarm* J. P. McMahon, 416,483. *Fire Alarm System*, J. Speicher, 416,513. *Electrical Signal Apparatus*, G. W. M. Conz, 416,572, December 3. *Electrical Annunciator*, F. S. Carter, 416,712. *Electric Door Alarm*, E. W. Taylor, 416,971. *Electric Indicator for Grain Bins*, A. C. Thompson and H. E. Newton, 417,117, December 10.

Clocks:—*Electrical Appliance for Winding Clocks*, F. A. Lane, 415,817. *Secondary Electric Clock*, E. L. Slocum, 416,148, November 26.

Conductors, Insulators and Conduits:—*Insulated Conductor*, J. A. Wetmore, 415,262. *Pole for Electric Wires*, L. R. Greene, 415,324 and 415,325. *Insulator for Electric Batteries*, C. Payen, 415,333. *Insulator*, G. Fowler, 415,504, November 19. *Joint for Coupling Underground Cables*, B. H. Wesslau and G. Trautwein, 415,751; B. H. Wesslau, 415,752. *Composition for Overhead Insulators*, S. H. Gilson, 415,864. *Insulating Hanger*, W. R. Park, 416,122. *Coupling for Underground Cables*, B. H. Wesslau, 416,143 and 416,144, November 26. *Distributing Box for Electrical Conduits*, E. S. Perot, 416,235 and 416,234. *Appliance for Insulating Electric Wires*, A. E. Ellinwood, 416,289, December 3. *Electric Conductor*, J. J. Saville and J. H. Winspear, 417,095, December 10.

Distribution:—*Electric Transformer*, E. Thomson, 415,749. *System of Electrical Distribution by Secondary Batteries*, S. C. C. Currie, 415,766, November 26. *Induction Coil Transformer, &c.*, E. Thomson, 416,762, December 10.

Dynamos and Motors:—*Dynamo-Electric Machine*, T. E. Daniels, 415,190. *Electric Motor*, H. B. Pullman, 415,350. *Armature Core for Dynamos and Motors*, F. F. Loomis, 415,363. *Governor for Electric Motors*, C. L. Jaeger, 415,641, November 19. *Armature Plate*, W. S. Belding, 415,695. *Coil Guard for Armatures*, same, 415,696. *Armature*, same, 415,697. *Lathe for Winding Armatures*, same, 415,805. *Armature for Electric Machines*, same, 415,806. *Dynamo-Electric Machine or Motor*, A. L. Riker, 416,013, November 26. *Regulator for Electric Motors*, N. S. Keith, 416,169. *Electro-Magnetic Motors*, N. Tesla, 416,191. *Method of Operating Electro-Magnetic Motors*, same, 416,192. *Electro-Magnetic Motor*, same, 416,193. *Electric Motor*, same, 416,194. *Electro-Magnetic Motor*, same, 416,195. *Magneto-Electric Machine*, W. H. Cooley, 416,443, December 3. *Commutator*, J. A. Dalzell, 416,720. *Coupling Electric Motors*, E. W. Rice, Jr., 416,746. *Compound Dynamo-Electric Machine*, F. B. Rae, 417,089, December 10.

Galvanic Batteries:—*Galvanic Battery*, J. E. Watson, 415,593, November 19. *Composition for Lining Electric Battery Jars*, O. A. Enholm, 415,962. *Galvanic Battery*, same, 415,963; G. Otto, 415,975, November 26.

Ignition:—*Gas Lighting System*, A. Lungen, 416,635, December 3. *Electric Gas Lighter*, N. Newman, 417,075 and 417,198, December 10.

Lamps and Appurtenances:—*Electric Arc Lamp Head Light*, R. T. McDonald and J. Cain, 415,252. *Incandescent Lamp*, J. Reese, 415,335. *Arc Lamp*, C. E. Scribner, 415,571 and 415,572. *Spark Arrester for Electric Lamps*, J. R. Farmer, 415,628, November 19. *Hanging Lamp Adjuster*, W. F. Bradner, 415,896 and 415,897. *Incandescent Lamp Socket*, P. J. Chassagne, 416,051, November 26. *Adjustable Support for Swinging Lamps*, Linwood F. Jordan, 416,368. *Suspending Device for Electric Lamps*, E. C. Dawson, 416,447. *System of Arc and Incandescent Electric Lighting*, W. Hochhausen, 416,611 and 416,612. *Incandescent Electric Lamp*, L. H. Leber, 416,632. *Shade or Reflector for Electric Lights*, W. B. Lawrence, 416,682, December 3. *Hanging Device for Electric Arc Lamps*, J. McLaughlin, 416,847. *Electric Light Support*, B. Schardt and W. Lutzenberger, 416,862, December 10.

Measurement:—*Electric Meter*, P. S. Bates, 415,491; E. W. Siemens, 415,577, November 19; E. Thomson, 415,747 and 415,748, November 26. *Compensating Electric Meter*, H. Lemp, 416,339. *Electric Meter*, E. Thomson, 416,350; M. L. Hansen, 416,604. *Galvanometer*, W. Thomson, 416,654 and 416,655, December 3.

Medical and Surgical:—*Electro-Therapeutic Appliance*, H. H. Kane, 415,274. *Electro-Medical Battery*, F. Moreton, 415,345, November 19. *Voltaic Belt*, F. A. Phillippi, 416,803, December 10.

Metallurgical:—*Process of Electro-Deposition of Metals*, W. Siemens, 415,576, November 19. *Process of Electrolytically Obtaining Copper*, H. A. Seegall, 415,738, November 26.

Metal Working:—*Electric Welding Clamp*, E. Thomson and J. Tregoning, 415,305, November 19. *Cutting Metal by Electricity*, B. C. Tilghman, 416,873. *Electrical Pipe or Metal Welding Machine*, H. E. Fowler, 417,013, December 10.

Secondary Batteries:—*Secondary Battery*, P. Kennedy and C. J. Diss, 415,327. *Electrode for Secondary Batteries*, C. Payen, 415,329. *Secondary Battery*, same, 415,331. *Process of Manufacturing Porous Metal Plates*, same, 415,330. *Mold for Casting Plates for Use as Electrodes of Storage Batteries*, same, 415,332. *Process of Producing Crystallized Metal Plates*, same, 415,347. *Method of Producing Crystallized Metal Plates*, same, 415,348. *Process of Producing Crystallized Metal Plates*, same, 415,349. *Method of Constructing Electrodes for Secondary Batteries*, W. H. Allen, 415,490. *Secondary Battery*, J. A. Wotton and W. R. Polk, Jr., 415,600, *Process of Producing Porous Crystallized Metal Plates*, C. Payen, 415,683. November 19. *Electrode for Secondary Batteries*, J. Y. Bradbury and F. J. Stone, 415,936. *Secondary Battery*, W. F. Smith, 415,981. *Method of Making Supports for Electrodes of Secondary Batteries*, W. F. Smith, 416,126, November 26. *Secondary Battery*, J. K. Pumpelly, 416,299. B. E. S. Covert and J. K. Pumpelly, 416,573. T. J. Haslan, Jr., 416,605, December 3. C. H. Logan, 417,055. *Method of Preparing Electrodes for Secondary Batteries*, J. K. Pumpelly, 417,088. *Secondary Battery Plate*, V. H. Ernst, 417,158, December 10.

Telegraphs:—*Telegraph Repeater*, R. J. McIlhenny, 415,417, November 19, *Telegraph Transmitter*, O. D. LaDow, 416,732, December 10.

Telephones and Appliances:—*Telephone Exchange System*, C. E. Scribner, 415,573, November 19. *Telephone Receiver*, J. W. Bonta, 415,700. *Circuit for Multiple Switch-Boards*, J. J. Carty, 415,765, November 26. *Test-Circuit for Multiple Switch-Boards*, C. E. Scribner, 416,275. *Telephone*, E. H. Lyon, 416,476, December 3. *Telephone Switch*, J. Sack, 416,754. *Testing Apparatus for Multiple Switch-Boards*, C. E. Scribner, 416,808. *Test-Circuit for Multiple Switch-Boards*. same, 416,809. *Telephone Transmitter*, J. C. Eichmeyer, 417,009. *House Telephone Exchange*, W. M. Goodridge, 417,018, December 10.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in January, 1890.

Reported for the Electrical Engineer, by F. B. Brock, *Patent Attorney*,
639 *F street, Washington, D. C.*

Fire Telegraph, F. Latta, 131,552, January 7, 1873. *Meter*, L. Bradley, 134,636, January, 7, 1873. *Duplex Telegraph*, J. B. Stearns, 134,776, January 14, 1873. *Printing Telegraph*, T. A. Edison, 134,866, January 14, 1873. *Automatic Telegraph*, T. A. Edison, 134,867, January 14, 1873. *Electro-Magnet*, T. A. Edison. 134,868, January 14, 1873. *Insulator*, N. Hendricks, 135,334, January 28, 1873.

[Drawings and specifications of any patent will be furnished by Mr. Brock at cost, 15 cents each.]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. IX. NEW YORK, FEBRUARY, 1890. No. 98

NOT AN AFREET.

THERE can be no doubt that the fatalities caused by contact with electric light wires in New York during the closing months of last year, followed by the general destruction, as public nuisances, of arc lighting conductors on the part of the municipal authorities, have tended to create or to emphasize in the public mind a feeling of some terror in regard to all electric conductors, and a suspicion that electric lighting, particularly, is intrinsically a too dangerous public and private convenience; a suspicion that the confessedly mysterious force employed is in its nature erratic and intractable; that, unlike other forms of energy, its behavior under given conditions is uncertain; that it is incapable of complete regulation and direction. The daily press, with customary recklessness in times of public excitement, has, with little knowledge and much lurid rhetoric, done its utmost to intensify alarm and to darken counsel. Newspapers have been stimulated in their irrational and misleading treatment of the dangers of electric lighting through the rivalry of competing companies; who have not been slow in supplying the ready-writers of the press with "points" against the systems and methods of their adversaries. The public is told that high tension currents and alternating currents carry death, and that low tension currents carry fire, along with their light through our streets and houses; till it imagines itself "between the devil and the deep sea," with no safety anywhere.

In the haste and tumult of the daily press—with a few conspicuous exceptions—discrimination and wisdom in the treatment of the topics of the day is no longer looked for; but those qualities are expected in the more deliberate utterances of men qualified by character and experience to lead or guide public opinion through their less frequent periodical writings.

From his "Easy Chair," which he has graced for so many years, and whence so many lovers of wisdom, moderation, wit and fancy have gratefully received a monthly allowance for half their lives, Mr. George William Curtis indites, and prints in *Harper's* for February, the following:—

> Our Uncle Sam plumes himself greatly upon his latest achievement—the electric light. But how many a hapless victim has been put to sudden death by the wretched wires in the streets of New York alone! The Boston fire was caused by these uncomprehended agents, and it is shrewdly suspected that the Brooklyn Tabernacle was kindled by them, and not, as was wildly suggested, by the fervor of the pastor's eloquence.
>
> The truth is that the electric light is an untamed afreet. Its laws are apparently ill understood. The courteous host who shows you through his noble mansion, *illuminato al giorno*, is evidently a little afraid of his nimble servitor. Candles and gas and the lamp of sperm or kerosene are familiars in the strictest sense. He anticipates no ill-turn from them save the malodorous consequence of neglect properly to shut off the gas. But the latest light-bearer seems to him uncanny and lawless, and nobody is qualified to instruct him how to control or subdue its antics. The law requires the wires to be buried in the city, and the newspapers peremptorily demand the execution of the law. But the chief of experts in the use of lightning, who is presumed to know all because the rest presumably know nothing, remarks that the wires of telephones and telegraphs and electric lights and the pipes of gas and steam will not make a subterranean happy family, but at any moment they may be mutually exasperated to a degree of fury which will hurl even the Equitable skyward. If the electric wires burn up Boston they will probably blow up New York, remarks the musing philosopher who precedes the New-Zealander upon the Brooklyn Bridge. But if you ask him what we shall do, he shrugs his unanswering shoulders.
>
> Last summer passed in a debate whether the recommendation of an accomplished commission, enacted into law by a presumably competent legislature, ordaining capital execution by electricity, must not be set aside as practically useless for its purpose. Yet if the ordinary wire chances to kill the innocent so readily, why should not the carefully directed force be fatal to the guilty? Counsel argued and judges pondered and the public wondered. The doubt of the new agent revealed again the perilous imperfection of our knowledge of the force which we have newly constrained to our service.

The wit and fancy of the "Easy Chair" are here in abundance; but where are the discrimination and the moderation? Has he not let his facile pen play with a subject which he has not taken pains to look into carefully? Ought he not to have learned that the electric light is *not* an "untamed afreet"; that the laws of electricity are *not* "ill understood," but well understood; that, like water and steam, its current and its pressure can be accurately measured; that its effects under given conditions can be accurately predicted and limited; and that it has caused destruction to life and property through the neglect of perfectly well-known precautions and safeguards; just as people are burned alive in railroad cars heated by stoves? Mr. Curtis's allusion to "candles and gas and the lamp of sperm or kerosene" is singularly infelicitous: they are indeed "familiars in the strictest sense"; familiar not less through their thousands of hapless victims than through the "malodorous consequences of neglect."

Mr. Curtis makes a point of the uncertainty of opinion among electricians, brought out in the Kemmler investigation last summer, in respect to the deadly effects of electricity, as "revealing the perilous imperfection of our knowledge of the force which we have newly constrained to our service." Every one knows that enough electricity will kill a man. We know that a fall from a sufficient height will kill a man. But because we are unable to say with certainty that a fall from the second or the third story of a house will kill a given person—although it usually suffices—do we reveal a perilous imperfection in our knowledge of gravitation?

Now the truth is that the "latest light-bearer" is no more "uncanny" or "lawless" than steam. Steam will rend any inadequate boundaries; so will electricity. Each, in sufficient quantity and under sufficient pressure, when let loose, carries death and destruction in its path. In both cases there is no doubt whatever in respect to the adequacy of well-known means of regulation and control. People are killed and property is destroyed, not because electricity is unmanageable; but because the average American takes too many chances, is more anxious to reach his point by the quickest and cheapest route than by the safest and best. Hence the notoriously defective and dangerous character of much of the electric light construction of the past. Let Mr. Curtis and other leaders of public opinion do their utmost to stigmatize cheap and adventurous electrical engineering, and to train the community to submit to no needless dangers, whether from electric lights, steam boilers, railways, or other instruments of civilization and progress, and they will accomplish far more towards securing better conditions of safety and convenience than can be achieved through ill-considered and sweeping statements on technical subjects.

No better testimony to the superiority of electricity to all other illuminants in the matter of fire risk is needed than the experience of the Boston Manufacturers' Mutual Insurance Co. In a circular recently issued by its president, Mr. Edward Atkinson, it appears that from 61 mills equipped with electric lights anterior to April 1, 1882, there had been received, up to that date, reports of 23 fires caused by the electric current. A careful investigation, made under the direction of Mr. C. J. H. Woodbury, resulted in the adoption of rules for construction and insulation, guarding against the dangers disclosed in the 23 fires reported. The rules were enforced in all risks assumed by the insurance company, and remain unchanged to this day, except in so far as additions to them have been made to meet the requirements of new forms of apparatus.

Mr. Atkinson is now able to report that since April 1, 1882, his company has received no notice of any fire that could be attributed to electricity in the case of any risk insured by his company. Electricity is now employed for lighting or motive power in more than 600 risks insured by the Factory Mutual Companies.

"Our experience, therefore," says Mr. Atkinson, "justifies the conclusion to which we came after the first two years of electric lighting, that, under proper safeguards, it is the safest method of lighting that can be introduced."

THE Special Committee appointed by the National Electric Light Association, at the convention of last August to memorialize the proper committee of Congress for the abolition of customs duties on copper, presented their petition to the Ways and Means Committee of the House of Representatives, January 16, together with a brief statement of reasons, which we print on another page. The committee are circulating printed copies of an auxiliary petition, to which they desire to obtain the signatures of companies, firms or individuals engaged in electrical or other industries in which copper is consumed. Any who have not received a copy, and who wish to sign, will oblige the committee by addressing either of its members, viz.:—C. A. Brown, 227 South Clinton street, Chicago; G. M. Phelps, 150 Broadway, New York; J. F. Morrison, 15 South street, Baltimore.

The mood of the present Congress cannot be considered very favorable to tariff revision or to reform of any kind. But whatever the chances for the abolition of duty on copper, we have yet to hear a word in favor of retaining it on its merits. The only reason we have heard assigned for letting it alone comes from certain manufacturers who consume large quantities of copper, and who frankly say they would be glad to see the duty go; but they or their friends or business associates, are interested in keeping up protective duties on other things, and they dread a general stirring up of the tariff.

THE situation of the electric lighting companies in New York has not materially changed during the past few weeks; arc lighting is practically at a stand-still; and an evening stroll through some of the principal streets and squares, with their blinking gas jets, is suggestive of by-gone days come again. Everybody is heartily tired of the Board of Electrical Control and all its works, and waiting for better days. Bumptious and bellicose Mr. Gibbens has left the board;—to meditate what fresh designs in the quiet of his tent?

We shall probably find a new scheme for some sort of electrical control for the city or state enacted before the year rolls around; but it will be no better than the present plan unless politicians are driven out and kept out.

WE print in this issue the second and concluding portion of Mr. Wm. L. Puffer's very interesting and suggestive "Data of Various Incandescent Lamps together with an Improved Method of Testing." The tables and plots bring out many points of importance; not the least of which is the desirability of some generally accepted understanding as to what precisely shall be meant by a 16 c. p. lamp.

In our March number a supplementary paper will be published, entitled "The Distribution of Light Around Incandescent Lamps, with Efficiency Tests," by Henry Hobart and Earl Gannett, with plots and additional tables by Mr. Puffer.

THE Electric Light Convention, to be held at Kansas City February 11–14, has work enough cut out for it to fill four days laboriously but profitably. It is understood that the programme, as printed in our January issue, will be carried out in full.

PERHAPS no electrician of continental Europe is better known to American electricians than Herr F. von Hefner-Alteneck, who for twenty-three years has been in the employ of the firm of Siemens & Halske in Berlin. It is a matter of some significance that after so long a connection with the greatest electrical house in Europe Herr von Hefner-Alteneck should leave them to cast his lot with whom?—in Munich.

ARTICLES.

A REVIEW OF MODERN ELECTRICAL THEORIES.[1]

BY PROFESSOR WM. A. ANTHONY.

The general phenomena of electricity are familiar to us all. As children we learned of the attraction and repulsion of electrostatic charges, of condensers, of insulators and conductors, of electric currents and electro-magnets, of telegraphs, electric fire alarms and electric bells, of the heating of conductors, and even of electric lights. We have long been familiar with the effect of the current on a magnetic needle, and with the attraction and repulsion of currents for each other. We have seen that these effects are manifested at a distance from the conductors which carry the currents, and we have been willing to believe that the distances at which these phenomena could be recognized were limited only by the want of sensitiveness of the apparatus through which the effects were manifested. Probably not many of us stop to think *how* these effects were brought about. We were content with a general statement of the relations of the phenomena, or, at least, with the determination of the direction and intensity of the forces due to a given conformation of current. We talked of the attractions and repulsions as action across space, and, if we thought of them at all as requiring any mechanism through which to act, we still felt satisfied when we had discovered and formulated the laws that govern the action of these forces.

It did not matter to us that attraction across empty space was unthinkable; it was enough that action took place, and that we could measure and, to a certain extent, control it. We constructed instruments and computed forces acting under certain conditions; we multiplied experiments and thought we had developed a vast science. But there have not been wanting, even among the earlier philosophers, some who could not feel satisfied with the idea of action at a distance. Experience gives no clue to any explanation of action of one body upon another at a distance, except through some intervening mechanism, and if we find cases where such intervening mechanism is not apparent, to say that in these cases action at a distance is taking place, is only to say that the action is unexplained.

Gravity acts upon the distant planets, and, we believe, upon the most distant stars; but it is not enough to say that gravity acts, that it decreases as the square of the distance increases, we want to know *how* it acts. By what means or through what medium does our earth reach out to the distant planets and affect their movements? These are the questions that the dissatisfied few have asked in the past, and to-day it is not the few but the many who would be glad to have the question answered. Faraday early taught us that the mere statement of the law of electrical attraction or repulsion was no explanation, and he sought the explanation in the action in the intervening medium. He demonstrated by experiments that have become classic, that the effect of induction depends upon the nature of the medium intervening between the conductors; a demonstration that here, at least, the intervening medium took part in the action and helped to determine the result. Magnetic and electro-magnetic phenomena were to Faraday also effects propagated through the medium; and Maxwell, following Faraday's work, subjected the whole matter to a searching mathematical analysis. It was necessary, in order to complete the theory, to assume the existence of a medium in which the forces were exerted; but, as a medium had already been assumed to account for the phenomena of light, it would hardly be scientific to assume another to account for electrical phenomena. But would not one medium suffice for electrical and optical phenomena as well? Maxwell showed how the question of the identity of the two media could be tested, and our modern views of electricity are mainly the results of his work. What do we *know* of electrical phenomena? We know that pieces of glass and silk rubbed together and then separated attract each other; that the property of attraction can be imparted to metals if they are insulated; that if two such masses of metal be connected by a wire the power of attracting each other disappears, and, at the same time, the wire is warmed and for an instant exerts magnetic forces at right angles with the wire. Numerous other facts we know, but these will suffice as illustrations of the phenomena. When a metal conductor is discharged by touching it with a wire we say the wire carries a current, and we have been accustomed to ascribe the heating and the magnetic effects to that current. We have looked upon the thing, whatever it is, that takes place in the wire as the origin of all that takes place around it. The current warms the wire, and it confers upon it the property of acting upon magnetic needles; but *how* does it act? We cannot conceive of the action of that wire on that needle, except through something extending from the wire to the needle through which the wire can exert a push or pull. All around that wire the needle is affected; at considerable distances the effect can be exhibited, and we believe it is only want of delicacy of our apparatus that prevents our discovering it at the greatest distances. If the wire acts it acts through a medium in which it creates a disturbance, and the disturbance in turn acts upon the magnetic needle. But are we sure that the action begins with the wire? Is it not possible that the action begins in the medium, and that the wire merely separates portions of the medium and so permits action that could not otherwise take place? Maxwell has proposed a mechanical illustration of the action taking place in space when electrical phenomena occur, and Fleming and Lodge have elaborated it and brought it within the reach of non-mathematical readers. Let us suppose all space to be filled with wheels connected by idle wheels in such a way that when one turns all must turn in the same direction, except that the elasticity of the system permits a small movement of one wheel before the others in the vicinity begin to move. Electromotive force is then something that tends to turn the wheels. Let *b* in figure 1, represent some source of electromotive force; *a* and *c* conductors, not forming a closed circuit but having an opening at *d*. The electromotive force at *b* tends to turn the wheels, but so long as the gap exists at *d* the wheels are connected through all space, and the E. M. F. at *b* can effect nothing except to turn the wheels through a small angle until the elastic resistance balances the E. M. F. In the conductor the wheels are not supposed to be rigidly connected. They can turn by slipping on each other, and the wheels in space may turn by slipping on the wheels in the conductor; hence, as the ends of *a* and *c* approach each other, the connection between the wheels within the enclosure and those of outside space becomes smaller and smaller, and, when the conductors touch, there is no longer anything to prevent the wheels within from turning, and they begin to spin in obedience to the E. M. F. at

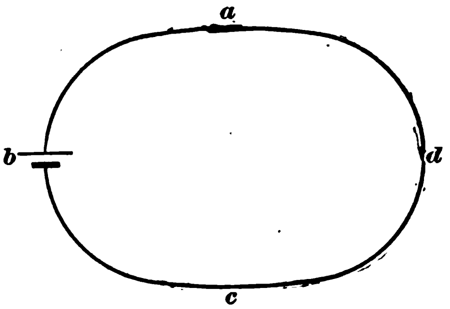

FIG. 1.

---

[1] Read before the American Institute of Electrical Engineers, New York, January 21, 1890.

b. The conductor is heated by the friction due to the slip of the wheels around and within it. The spinning of the wheels constitutes the magnetic forces if we assume the wheels, originally spherical, to become flattened spheroids by the spinning, and to be forced to remain in contact at their poles. Assume the wheels to have inertia, and it will require time for them to reach their full velocity, and the time will be greater as the number of wheels is greater, that is, as the magnetic forces developed are greater. On the other hand, the wheels will not at once stop if the electromotive force is removed, and if the conductor be broken at some point, allowing the rapidly spinning wheels enclosed by it to come in gear at that point with the stationary outside wheels, there will be, for a brief time, until the moving wheels can be brought to rest, a clashing and disruptive action known as the extra spark.

I have spoken of the heating of the conductor as due simply to the friction of the spinning wheels upon the wheels within the conductor. The greater the friction the greater the motion imparted to the wheels within the conductors and the greater the heating. The less the friction the less the heat, and if there were a substance whose wheels could revolve among themselves and against the wheels of space without friction, such substance would form a perfect conductor which would offer no resistance to the motion of the wheels in the space enclosed by it, and however rapidly those wheels might revolve they would have no influence to produce motion within such a conductor. We are led, then, to this, that a perfect conductor, instead of being a substance in which any E. M. F. produces an infinite flow of electricity, may be a substance in which no effect whatever is produced.

I do not present this as representing the real activities involved in electrical phenomena, or as a theory by which all electrical phenomena may be explained. I give it as bringing prominently into view the activities in the medium surrounding the conductor; whereas, the language in which we usually describe electrical phenomena points to the conductor itself as the seat of the electrical forces. Whatever our theory, we know that something does take place in the medium that surrounds the conductor. We know that were a heavy current to flow through a conductor in the most distant part of this room a delicate needle here on the table would show that a magnetic field was produced here. We are certain that magnetic lines of force from the electric currents on our streets, whether overhead or underground, permeate this room, and traverse our bodies, even though we have no sense through which we can become directly conscious of them. Take in your hands two wires connected to the poles of a battery or dynamo and touch their ends together. You see a flash of light, the wires become warm, they attract iron filings; coiled into a spiral they will attract with great force large masses of iron; two such spirals will attract or repel one another. What more natural than to say, Here in the wire is a new activity which warms it and confers upon it magnetic properties? What more natural than to forget or fail altogether to recognize the activities in the space around; activities that do not impress any of our senses; that do not wrench our arms, or burn our flesh, or blind our eyes; and yet it is well to fix our attention for a while upon the space that the conductor encloses, and recognize the fact which the little delicate needle demonstrates to us, that something is going on in that space, something quite as important, perhaps more important, than that which takes place in the conductor.

Whatever the magnetic forces are, we know they cannot be called into existence instantaneously. Time must always elapse before the full effect of an electric current is felt, and the greater the forces developed the longer are they in reaching the maximum. Moreover, the current in the wire cannot be developed at once; it keeps pace with the magnetic force and reaches a maximum only when the magnetic forces reach a maximum. This is exactly what would follow if magnetic forces result from the setting in motion of wheels possessing inertia. Whatever magnetic forces may be, they begin and end like the motions of massive bodies.

Continuing our hypothesis, an electromotive force would be anything that tends to set the wheels in motion. The wheels are set in motion if a limited number acted upon by the E. M. F. are separated by a conductor from the other wheels of space; but, even if they are not separated, that is, if the conductor does not form a closed circuit, the wheels are rotated through a small angle, depending on the elasticity of the wheel work. This displacement constitutes an electric charge, the tendency of the wheel work to spring back is *difference of potential*, and this difference of potential is maintained by the E. M. F. Here allow me to call attention to the distinction between difference of potential and E. M. F. I often see statements that indicate that the distinction is not clearly kept in view. In that excellent little volume, the Dictionary of Electrical Terms, the statement occurs that electromotive force is *due to* difference of potential. It should rather be difference of potential is due to E. M. F. Difference of potential is *an* electromotive force, but not all electromotive forces are difference of potential; and, furthermore, I can think of no case of difference of potential that does not owe its existence to some other electromotive force *not* difference of potential. Difference of potential is a moving force acting from within. Electromotive force acts from without. Difference of potential results from a changed electrical distribution, an electric strain, and represents the tendency to return to the state of equilibrium. Electromotive force is the something from without that produced the electric strain. Consider our wheelwork illustration. I may seize a wheel here and turn it, but I can only turn it through a small angle before the elastic forces, brought into play by the distortion, balance the force that I am able to exert. My force is electromotive force, the elastic forces are difference of potential. Let figure 2 represent a voltaic cell with its copper and zinc plates and dilute acid; we know that something takes place by which the copper becomes positive and the zinc negative, and, if the copper and zinc be joined by a wire, electricity is said to flow from the copper to the zinc through the wire, and from zinc to copper through the liquid. The flow through the liquid used to be explained by assuming the zinc to be positive and the copper negative within the liquid; just the reverse of what we find without. But connect the copper to the zinc by a wire within the liquid: the current flows through the wire from the copper to the zinc. The copper, therefore, is not negative, but everywhere positive. Then why does the current set from the zinc to the copper through the liquid? Because there is an electromotive force, not difference of potential, mind you, for the difference of potential tends to cause a flow the other way, but a something that forces the current through the liquid against the electric pressure. The cell is an electric pump that pumps electricity from the zinc into the copper until the pressure becomes so great that the pump stops. Open a passage from the copper to the zinc by connecting the two by means of a metallic wire, the electricity flows and relieves the pressure, the pump begins to work and so maintains a continuous flow. No; E. M. F. is not difference of potential, although difference of potential is E. M. F. It is even possible to produce an electric current without any difference of potential whatever in any part of the circuit, just as it is possible to produce a flow of fluid without any difference of pressure.

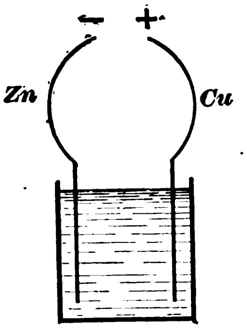

FIG. 2.

Whatever difference of potential may be, it behaves like a force developed by an elastic displacement in a solid body. Whatever magnetic forces may be, they behave as though produced by the motions of inert masses. An electromotive force, suddenly brought to bear at a given point, has to overcome not only the elastic force but the magnetic inertia. In other words, an electromotive force, tending to produce current, immediately develops a difference of potential against which it must act, and also develops magnetic forces which retard its action; so a *fluid-moving force* meets opposition in the elastic force of the fluid and in the inertia of its particles. But the effect of any such force is propagated through the medium with a finite velocity expressed by the well-known formula,

$$V = \sqrt{\frac{E}{D}}.$$

Electric displacements ought, therefore, to be propagated with a finite velocity which should have some relation to the ratio between the electrostatic effects, analogous to elastic displacements, and the electro-magnetic effects, analogous to the effects of moving masses. You all know that it is shown that this velocity is expressed by the ratio of the magnitudes of the electro-magnetic and electrostatic units quantity, and you know also that determinations of this ratio show it to be the velocity of light. This determination gave a very strong support to Maxwell's electro-magnetic theory of light, and, coupled with the fact that observations, so far as they went, indicated that magnetic effects are propagated from the sun to the earth with the same velocity as light, made the theory at least extremely plausible. But within two years the wonderful experiments of Hertz have demonstrated beyond question that electro-magnetic waves travel through space from every source of alternating currents or potentials, and that the waves travel with the velocity of light. In this city there are, I suppose, many alternating current systems. When we think of these in action we are apt to think only of the activity in the conductors of the machines, the lines, the transformers, the lamps, and yet we know that in all the space around there is activity. Waves are chasing each other through this room, through our streets, our houses, our offices. They are everywhere present. We are bathed in this agitated medium every moment, and yet we live, and not only live, but are totally unconscious of the activity that surrounds us. No sense responds to the wave motion that fills this space. And yet, when these waves become short enough and frequent enough, they do affect our sense of vision and a vast array of phenomena that otherwise would have had no existence for us, are made known to us through this special sense. But the eye only responds to waves of $\frac{1}{70000}$ to $\frac{1}{37000}$ of an inch in length, while the length of the waves emitted by one of our alternating current systems is 600 miles. The waves that affect the eye must occur at the inconceivable rate of at least 400 millions of millions per second, while less than 300 waves per second are emitted from our alternating systems. These waves come very far short of the number necessary to effect any of our senses; but we have been able to demonstrate their existence; at least we have been able to show that something possessing all the characteristics of wave motion exists in the space around a source of alternating currents or potentials. It is something to know that waves of such enormously different lengths and frequencies exist in the medium that is agitated by waves of light. It is something to understand that our sources of alternating currents are centres of radiant energy, differing from light only in wave length; and since we have begun to appreciate this fact, we have often asked ourselves the question: Can the rate of alternation be increased until the whole apparatus should glow with light? Although the enormous rapidity required seems to render this direct solution impossible, it seems to me there must be a way to obtain the light we want without all this waste of energy. I cannot believe it will always be necessary to develop waves of all lengths, from many miles down to a hundred thousandth of an inch, in order to obtain the narrow range of wave lengths by which we see. I do not know of any practical way of obtaining the few wave lengths that constitute light without at the same time producing the others, but it *is* done. The glow-worms do it, the fire-flies do it, the lantern beetles do it, and I believe the time is coming when man can do it. Instead of getting 10 16-candle lamps per horse-power we ought to get 200. I don't know how it is to be done. I don't expect we are going to make alternating machines to produce 500 millions of millions of alternations per second. But possibly we may solve the problem indirectly by the use of some substance having a special rate of vibration, such as the gases. Possibly we may be able to excite electrically the fluorescent salts. Possibly we may be able to charge and discharge a condenser and take advantage of the oscillatory discharge to set up vibrations of the frequency required. Possibly we may discover the secret of the glow-worm and fire-fly and substitute electric for the insect energy. I know it will take several fire-flies to equal a 16-candle lamp, but it will also take a good many fire-flies to develop a horse-power. But although I do not see at present any practical solution of the problem, I repeat, I believe the problem can and will be solved. We are not going on forever burning a coal mine whenever we want a little light. Neither are we going on forever converting the energy of coal into heat when it is mechanical or electrical energy we want. From the very nature of things not more than one-fourth or one-third the heat so produced can be transformed into any other form of energy. The energy of fuel *can* be converted into mechanical energy without first becoming heat. It *is* so converted in every animal movement. The way exists; let us find it. Find this, and the way to make light only when it is only light we want, and we shall have lengthened the life of our coal deposits five or ten times. The man who solves either one of these problems will be the greatest discoverer of this or any other age. If he gets a broad patent on it, he will have seventeen years of the grandest litigation the world ever saw.

Now I can imagine that some electrician will consider that the first part of this paper dealt with matters that are of no practical consequence in the use of electric currents. Of what practical consequence is it whether force is conveyed to a distance by means of a medium or simply acts at a distance. What does it matter whether electric energy is conveyed by the conductor or through the dielectric? We know how to proportion and dispose our conductors to produce a given effect, and that is enough. But consider what we have learned already of the intimate connection between light and electricity, and I think you will agree that the more we know of the ultimate nature of electricity the nearer we shall be to the solution of the great problem to which I have referred, and the solution of either one of those problems would revolutionize some of the most important industries of the world. May not the solution of at least one of these problems be accomplished and the results exhibited at the great exhibition to be held in New York in 1892? What a wonderful achievement it would be to light all those great buildings without waste, heat, or drive all that vast array of machinery without a fire!

.... AT present the best dynamos are made by experienced mechanical engineers who have somehow picked up a working knowledge of electricity.—*John Perry.*

.... IN the earlier days of railways and telegraphs, not only had altogether new edifices to be erected, but the material out of which they have been constructed had to be searched for and discovered.—*S. Alfred Varley.*

.... IF the plant is to be run on proper principles of economy not a fire should be built, not a day's run made, without a perfect record being kept of the weight of every shovel of coal and every ounce of refuse left from the burning.—*C. C. Haskins.*

A study of these tables and plots will make it very evident that there is no commonly accepted value of a candle-power, or, if there is, that different makers vary widely in their attempt to produce it. The question, "What is meant by a 16 c. p. incandescent lamp?" has not, I believe, been settled by the courts, and until it is, there will be endless dispute as to whether a given lamp is "up to candle-power or not."

For example, take the Edison 101-volt 16 c. p. lamp; if we rate it by the light given off "on the face of the loop," *i. e.*, the standard reading, it is evidently 13.00 c. p., but if we select a point 45° from this it is about 19.00 c. p.; if we try to do better and take the mean horizontal candle-power then it is 16.46 c. p., or if we wish to take the mean spherical candle-power we find it to be 13.25 c. p. The watts in all cases being 79.58 we can sell this lamp as either 7.71, 4.09, 4.84, or 6.00 watts per candle.

It is, I think, commonly understood that the lamps of the Edison company are rated according to the following definition of a 16 c. p. lamp. A new 16 c. p. lamp will, when run at the number of legal volts indicated by the number on its base, give out light which, at a point on the horizontal circle 45° from the shanks, will be equal to 16 standard candles. This one point is taken to represent the mean horizontal candle-power. It will be noticed that the Edison lamps tested come fairly close to this rating, and also that the other lamps do not, indicating that the other makers do not understand a 16 c. p. lamp to be the same thing that the Edison company do.

It would be a great advantage to all parties if some authoritative statement of what is meant by the candle-power of an incandescent lamp could be made, and thus settle at once the uncertainty now existing.

ROGERS LABORATORY OF PHYSICS,
Mass. Inst. of Technology, Dec., 1889.

THE EAST END ELECTRIC LIGHT COMPANY'S STATION AT PITTSBURGH.

Since the East End Electric Light Company, of Pittsburgh, Pa., has finished its arc light plant, its central station has become one of the most extensive and complete electric lighting plants in the country.

Commencing with a very small number of lights, supplied by the direct current system, about three years ago, the station has kept on growing until the buildings now cover an acre of valuable ground, stocked with machinery, supplying current to no less than 16,000 incandescent and 480 arc lamps.

Its history may be very interesting, not only to electric light engineers and managers, but also to persons who contemplate the establishment of an electric light plant.

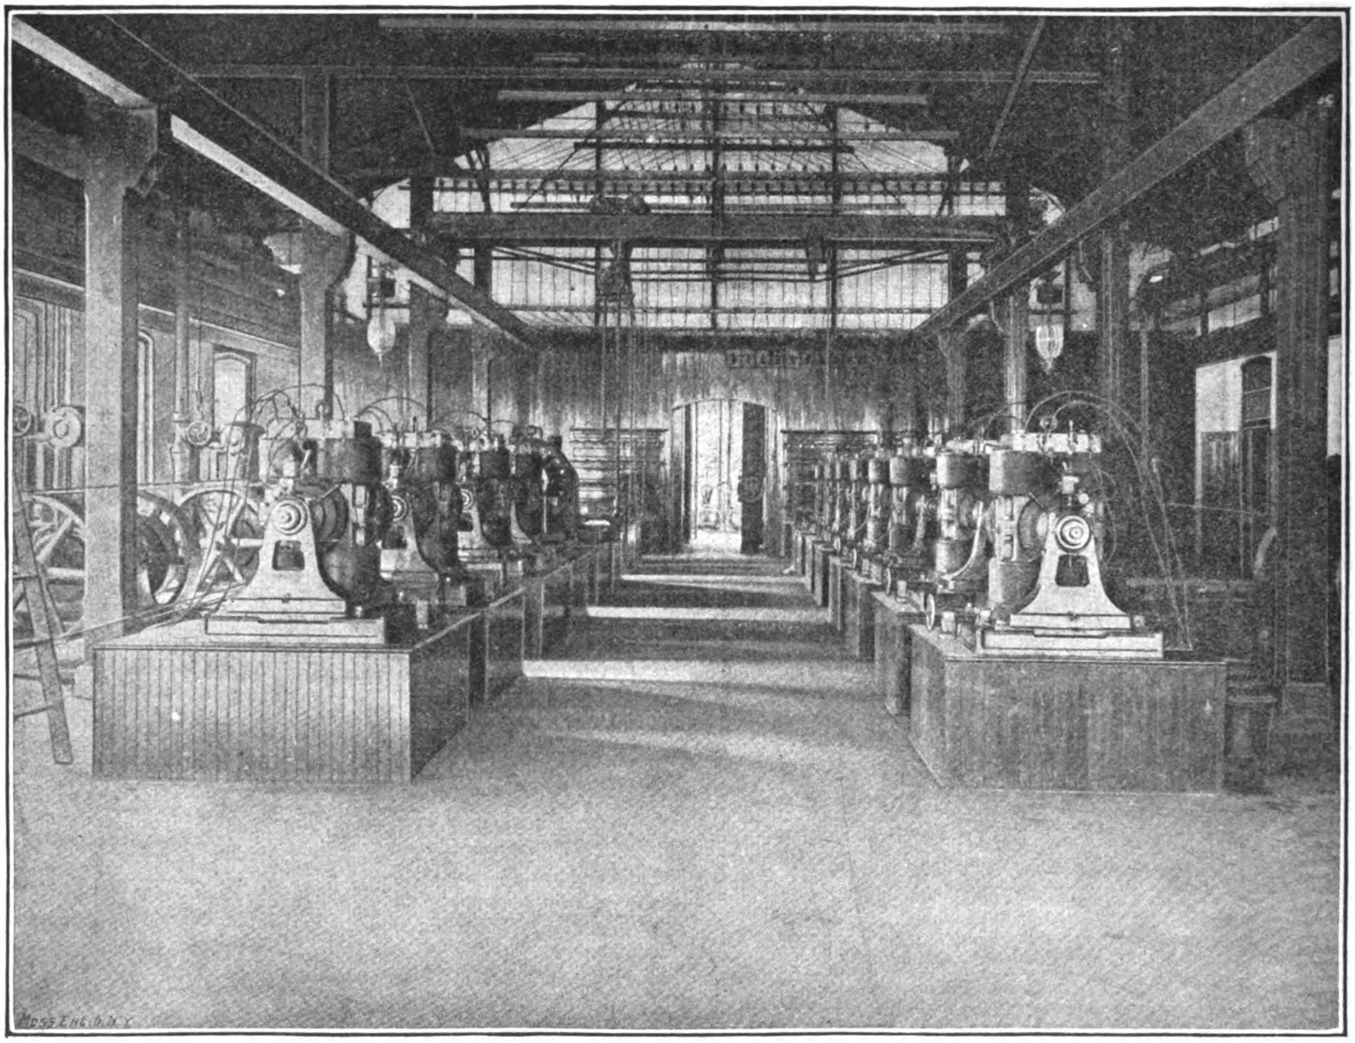

Fig. 1.—The East End Electric Light Company's Station, Pittsburgh, Pa.—Arc Dynamo Room.

The East End Electric Light Co. was organized January 20, 1886, and began operations with a 300-light Westinghouse direct current dynamo and a 45 h. p. Westinghouse automatic engine. This plant continued in use for over a year, during which period the increase of business and corresponding outfit was very slow. In consequence, the directors of the company decided in June, 1887, to adopt the Westinghouse alternating current system, which had been successfully introduced throughout the country during the preceding year, and had already gained well established favor. A new building for the central station was erected on Broad street, East End, and this structure was soon equipped with Westinghouse alternating current apparatus for a capacity of 3,900 lights. Two 1,300-light dynamos were placed in position, as well as two 650-light machines, with two 150 h. p. and two 75 h. p. Westinghouse automatic engines. In addition, the plant included two Westinghouse No. 8 exciters driven by two 25 h. p. Westinghouse automatic standard engines. Four 100 h. p. Riter & Conley boilers constituted the steam battery of the plant. The most improved electrical appliances were utilized in fitting up the station, and when in March, 1888, operations were commenced, it was generally conceded that the East End company possessed a model electric lighting plant.

From the first day of its operation evidences of the success of the new plant were everywhere recognizable. The alternating current system of distribution effected marked improvement in meeting the demands of the service, and the business of the company increased very rapidly. The furnishing of electric lights to private houses was immediately undertaken, and in that direction marked success was the result. Applications became so numerous and so urgent that repeated enlargements of the plant had to be made. When the company found itself thus securely placed upon a solid basis of business, the management deemed it advisable to enter the field of arc lighting. A lot adjoining the incandescent station was purchased, and in February, 1889, ground was broken for the building which now contains the arc light plant. This outfit was completed a few weeks ago, and the two electric light buildings, with their contents of incandescent and arc apparatus, are briefly described below.

On entering the arc light building from Broad street the visitor instinctively halts at the threshold to enjoy the interesting vista before him:—a spacious, lofty, well-lighted hall, filled, but not crowded, with machinery conveniently and symmetrically disposed. The floor is covered with asphalt, and as smooth as a skating rink. Standing at the door two rows of arc light dynamos arrest the observer's attention. There are six Waterhouse arc light dynamos, of 35 lights capacity each, on either side, and at the farther end is a new 60-light machine of the lately devised Westinghouse arc light system.

Behind the machines runs an underground conduit, into which all the wires from the dynamos are conducted. From this conduit they go to the switch-board, and from there to the top of the building into a cupola, from which they are distributed to the overhead mains on the adjoining streets. A door from the dynamo department leads into the boiler-room. There are two batteries of two Babcock and Wilcox boilers, each 240 h. p. The boilers are so piped that each boiler or each battery can be used independently or all together. The boilers are supplied with natural gas fuel at a uniform pressure of twelve ounces.

The engines are all furnished by the Westinghouse Machine Co., the directors of the East End company preferring them for their great efficiency and economy, as well as their convenience. There are four "Compound" engines of 80 h. p. each; three "Automatic" of 75 h. p. each; and one "Automatic" of 60 h. p.

The arc light house has been built to admit of machinery for a capacity of 1,000 arc lights.

The incandescent light building is large enough to hold six 3,000-light alternating current machines and two exciters. The present complement consists of five dynamos, viz.:—two of 3,000 lights capacity, two of 1,500 lights, and one of 750 lights. The present outfit of engines is as follows:—one "Compound," 250 h. p.; one "Duplex," 250 h. p.; six "Automatics," viz.:—one 200 h. p.; two 150 h. p.; one 125 h. p.; and two 25 h. p. The machines are arranged in a manner similar to that employed in the arc light station house. Everything has been arranged on one floor, and from any point in the room the entire outfit of machines and apparatus can be overlooked. The advantage of this is obvious when it is considered that on this account the force of attendants can be reduced to a minimum. Only one engineer and one fireman are required during the day, while at night but two engineers are necessary. This concentration of apparatus, together with the relatively little attention required by alternating current dynamos, enables the East End company to man its station with a remarkable economy in the labor account.

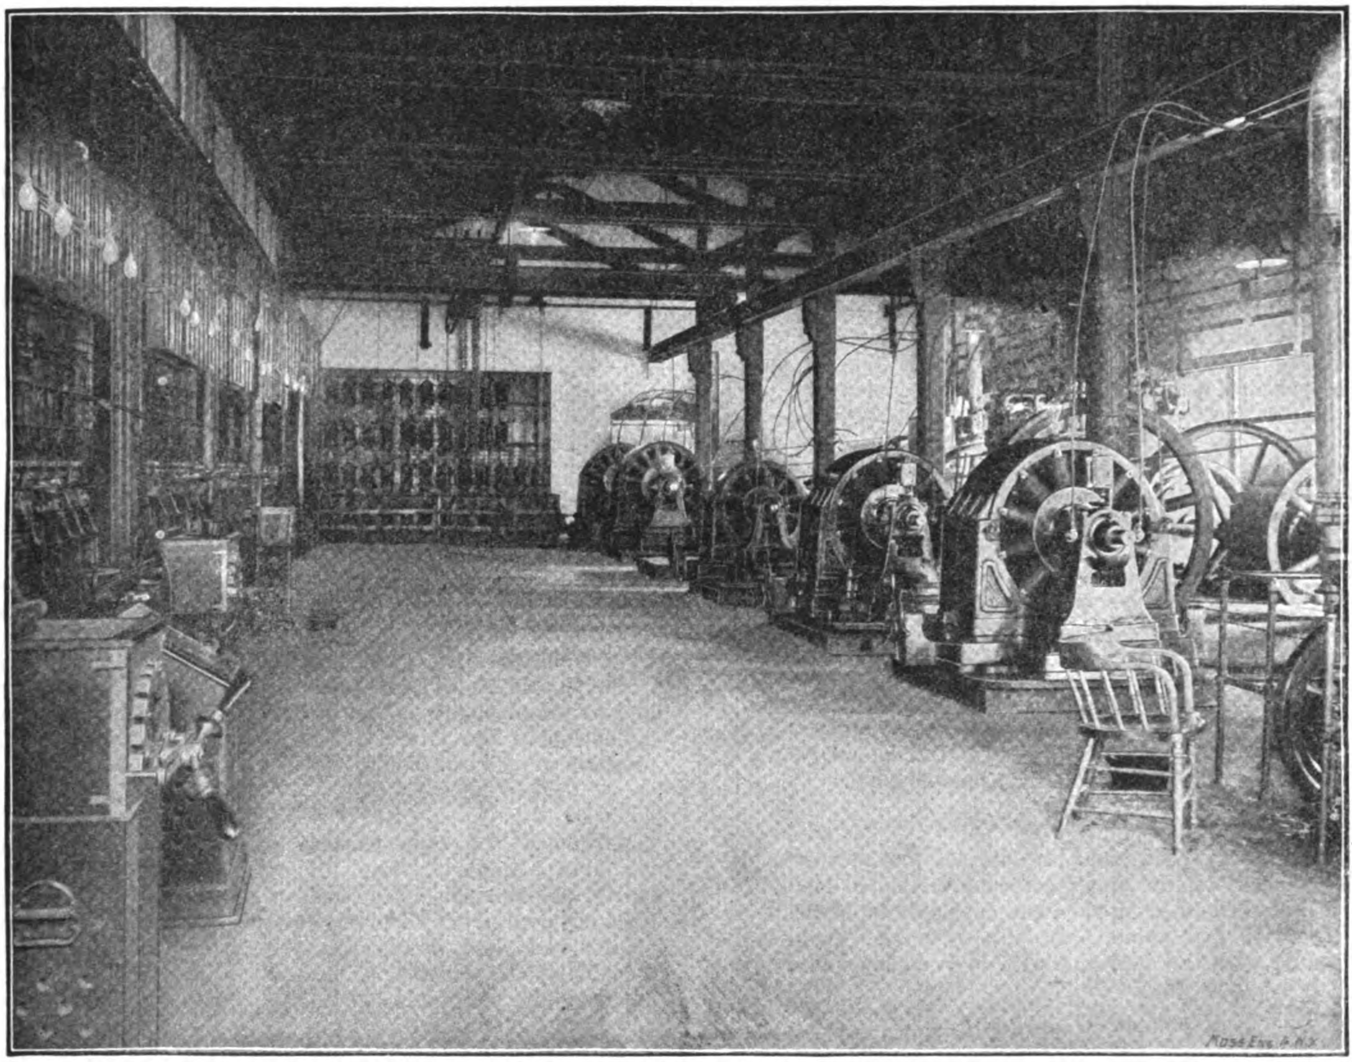

FIG. 2.—THE EAST END ELECTRIC LIGHT COMPANY'S STATION, PITTSBURGH, PA.—INCANDESCENT ROOM.

The company is a pioneer in supplying incandescent lamps to private residences. Four hundred houses, with 7,000 lights, are now served from its station. All customers of the company are furnished with an alternating current meter. The company also supplies fourteen churches with the electric light. The most distant incandescent lamp is situated five miles from the central station.

The switch-board in the incandescent station also deserves mention on account of its extremely convenient arrangement for ready manipulation. All the switches are placed in a single row on one wall.

INVESTIGATION OF THE MAGNETIC SUSCEPTIBILITY OF VARIOUS SORTS OF IRON AND STEEL.[1]

BY W. NEGBAUR.

I.

During the winter of 1888–89 I compared the magnetizibility of various kinds of iron and steel, and, as the subject is an important one, I give herewith my results, even if they are not all new.

The curves for the magnetism were investigated from their beginning all along their path to a magnetizing force of 50 C. G. S. units. Observations were made with two samples from each of twenty-two different kinds of iron and steel. All the samples were turned to uniform bars 80 mm. long and 5 mm. diameter. The measurements were made in the first position of Gauss, with mirror magnetometer, telescope and scale; the effect of the magnetizing coil being counteracted in the usual manner by a second spool. In all, about eighty series of observations were taken, each series consisting of the following: *First*, the combined effect of the two coils was reduced to zero (this being verified by the use of various strengths of current), and then the rod laid in the spool. I then let the current increase gradually from zero to the maximum the wire would admit of, during which process sixteen deflections and the corresponding currents were observed. The current was commutated and again gradually brought back to zero, during which time, at eight stages, as many observations were made with the now opposite magnetism.

The values, however, for the specific magnetism shown in table 5 are for *increasing* current, so that it is possible to compare the different curves with one another. With decreasing current, the values for the magnetism of the steel rods, by reason of the residual magnetism, fall more slowly than those of soft iron pieces, so that a glance at the different curves would give a false idea of the general susceptibility of the various sorts of iron.

II. NOTATION AND PRELIMINARY CALCULATION.

Let

M = magnetism, in C. G. S. units.
H = horizontal *intensity of earth's magnetism.*
r = distance in cm. of sample from magnet.
n = number of windings on the spool.

(1) Calculation of the magnetizing force.

The average weight of the samples was 13 grams. If we demand as a maximum, a specific magnetism of 180 C. G. S. for the best sorts of iron, then the magnetic moment of a rod is 13 × 180, or about 2,400 C. G. S. units. From Müller's formula with the constants of von Waltenhofen.

$$M = 14.4\, l\, d^2 \text{ arc } tang\, \frac{n \sqrt{l}}{5300\, d^{\frac{3}{2}}}\, i,$$

and the magnetizing force $n\, i$, for $M = 2400$, is

$$n\, i = 7500 \text{ C. G. S.}$$

(2) Calculation of distance of rod from magnet.

In order to retain the scale in the field of the telescope, the distance r, of the bar from the magnet, was calculated from the equation

$$tang\, \alpha = \frac{2\, M}{H\, r^3}$$

when, for the greatest allowable deflection of 50 cm. the scale was removed 160 cm. from the mirror.

Then
$$r = \sqrt[3]{\frac{2\, M}{H\, tang\, \alpha}},$$

and by substituting these values ($M = 2500$; $H = 0.186$ and $tang\, \alpha = \frac{a}{2\, b} = \frac{50}{2 \times 160}$) r = nearly 60 cm. M is purposely taken larger, as the above formula gives too small dimensions for our rods.[2]

III. PLAN OF THE EXPERIMENT.

The magnetizing force was induced by means of a bobbin with a cylindrical opening for the magnet. The dimensions of the bobbin were:—Length, 8.4 cm.; external diameter, 3.8 cm.; internal diameter, 0.8 cm., the winding being 504 turns of 1.2 mm. wire with single cotton insulation—the wire carrying as a maximum 15 amperes. The maximum current demanded an arrangement for cooling the bobbin, and this, after many trials, was satisfactorily accomplished by dropping oil. The second bobbin, *k*, was as nearly identical in every respect with the first as it was possible to make it. It lay, however, not rigid like K, but was movable, to allow its action being made equal to that of K. Besides this, K was set somewhat lower than K, so that the image of the scale could be seen in the telescope. The arrangement of the apparatus was as represented in figure 1. The spool K would alone excite a system of lines of force. By the addition, however, of the spool *k* the lines of force excited by K would be forced back, allowing the mirror to stand in the "indifferent" points of the two bobbins. The mirror and its magnet now being horizontal to the bobbins, any deflection of the mirror would depend upon the magnetic moment of the iron bar inserted in K.

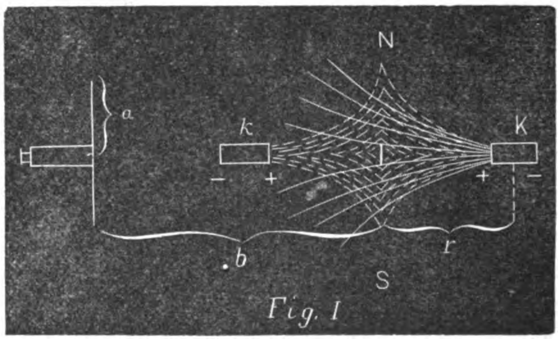

Fig. I

IV. CORRECTIONS.

Although the rods became warm when excited, yet we may neglect the influence produced by the rising temperature, as the inaccuracies lie always within the limits of error. The slight irregularities in the form of the rods had, however, a very great influence. The lengths of these were so exactly alike, that the difference in the magnetic moments must be ascribed to varying thicknesses.

These thicknesses being difficult to determine, the corrections were made with the greatest accuracy by simply considering the weight. Curves were constructed for the magnetic moment of each of the two samples of the same metal. The average difference corresponded to the difference in the weight of the samples, and this could be determined to any desirable degree of exactness. The mean of the differences between the various pairs of curves gave, when referred to the unit of weight, a constant, by the help of which the mean of the magnetic moment of two similar rods was corrected.

All values were calculated in percentages. If, for instance, the average of the weights of two similar samples was 2 per cent. greater than the average of the whole number of rods, then the values for a curve which was to be the mean of these two curves were reduced by twice the amount of the constant (in percentage).

It will be noticed that some values of the corrections expressed in units of weight, show important deviations, yet the mean of these corrections would not be very much influenced by this circumstance.

V. CALCULATION.

Let
a represent corrected deflection in mm.
b represent distance of scale from mirror in mm.
In the 1st position of Gauss

$$M = \frac{tang\ \alpha\ H r^3}{2} \text{ when } tang\ \alpha = \frac{a}{2\ b}$$

Therefore,

$$M = a \frac{H r^3}{4\ b}$$

Finding the value of the expression $\frac{H r^3}{4\ b}$ gave me a constant which is dependent only upon the horizontal intensity of the earth's magnetism, and upon the manner of setting up the apparatus. In the present case, when $b = 1610$, the expression $\frac{H r^3}{4\ b} = 6{,}239$. The magnetic moments were reduced to units of weight. The specific magnetism, M_s (that is, that magnetic moment which one gram of iron receives with a certain current), was found by dividing the constant by the average weight of the bars. This weight was, 13.112 grams.

Therefore,

$$M_s = a \frac{6.239}{13.112} = a \times 0.4757.$$

The deflections, corrected according to IV., are presented in the following table. Each corrected value having been multiplied by the above constant, 0.4757, the figures give, consequently, the specific magnetism.

The figures above the double line give the magnetizing force in absolute units.

That this iron is capable of being cast makes it especially suitable for the construction of dynamos and transformers. Of all the steels those of Bessemer and twice-refined "Loewen" steel proved themselves the most readily magnetized. The greatest difference observed in the samples examined was 31.6 per cent.

VI. RESULTS.

In the accompanying plate are sketched some curves taken from the table. The cast iron sorts occupy the most unfavorable place, the steels the middle, and the soft irons the best place.

The single, and very important exception to this, is the case of the ingot iron, which, at least in the sample used, showed a magnetic capacity as high as the best soft iron. I verified the results respecting the high magnetibility of this ingot iron by repeated measurements with numerous other samples from the same establishment (that of Peine, near Braunschweig). Nevertheless, this iron did not show such a high degree of magnetization as similar iron from the Westphalia Union. The place then, of the ingot iron lies between the steels and the soft irons.

Magrini[3] finds that by a magnetizing force of over 50 C. G. S. units the magnetic moment is independent of the kind of iron. In my experiments I have gone as high as a magnetizing force of 60 C. G. S. units, and my results have proved what Ewing showed, namely, that the course of the curves for the magnetism to a maximum is dependent upon qualities of the iron.

Finally, I wish to express my grateful thanks to Professor Dr. W. Kohlrausch for the kind help which he was ever ready to grant me.

Electrotechnical Institute of the Technical Hochschule,
in Hanover, Germany, April, 1889.

THE THOMSON-HOUSTON ARC-LIGHT SWITCH-BOARD FOR CENTRAL STATIONS.

A WELL designed and soundly constructed switch-board is one of the most important appliances required in the operation of arc light machines. There are but few central lighting stations in which commercial and street lights are not operated, making it necessary for convenience and economy to place two or more circuits in series on one dynamo, to transfer circuits from one machine to another, and to make such combinations of dynamos and circuits as local conditions render necessary. It is most desirable that there should be no extinguishment of the lights while these changes are being made, and that the construction of the board be such as to insure the operator against receiving a shock during manipulation. The switch-board here shown is designed to meet these requirements, is incombustible, and is of such construction that additions can be readily made from time to time without necessitating any changes in the part of the board having circuits already in position.

As will be seen from the illustrations, the board is made of two rectangular slate slabs, placed about five inches apart, into which are fitted rows of metal bushings; those arranged horizontally on the front board being connected to the dynamos, while the vertical rows on the back are connected to each other and the circuits. On the back there is one more row of bushings than on the front; this extra row being used to connect one circuit with another by means of the transfer cables and plugs.

The switch-board is made for four and six circuits, and is so arranged that additions may be easily made in which the number of dynamos and circuits provided for will be a multiple of four or six. The positive and negative terminals of the dynamos are connected to the left and right side respectively of the front board, and the circuits on the rear board in a like manner, the left being positive and the right negative, the bushings for the dynamos being numbered vertically, 1, 2, 3, 4, while those for the circuits are numbered horizontally, 1, 2, 3, 4. To connect a machine to a circuit the plugs are pushed through the holes on both positive and negative sides of the board, corresponding to the dynamo and circuit desired. To connect any two circuits in series on one dynamo before the machine is started the plugs are pushed through the holes corresponding to positive of one machine and one circuit, and then, by means of the transfer cable and plugs at the bottom of the rear board, the negative of this same circuit is connected to the positive of the second circuit which it is desired to place in series with the first, the final connection being made by pushing the plug through the hole corresponding to the negative of the second dynamo and negative of second circuit.

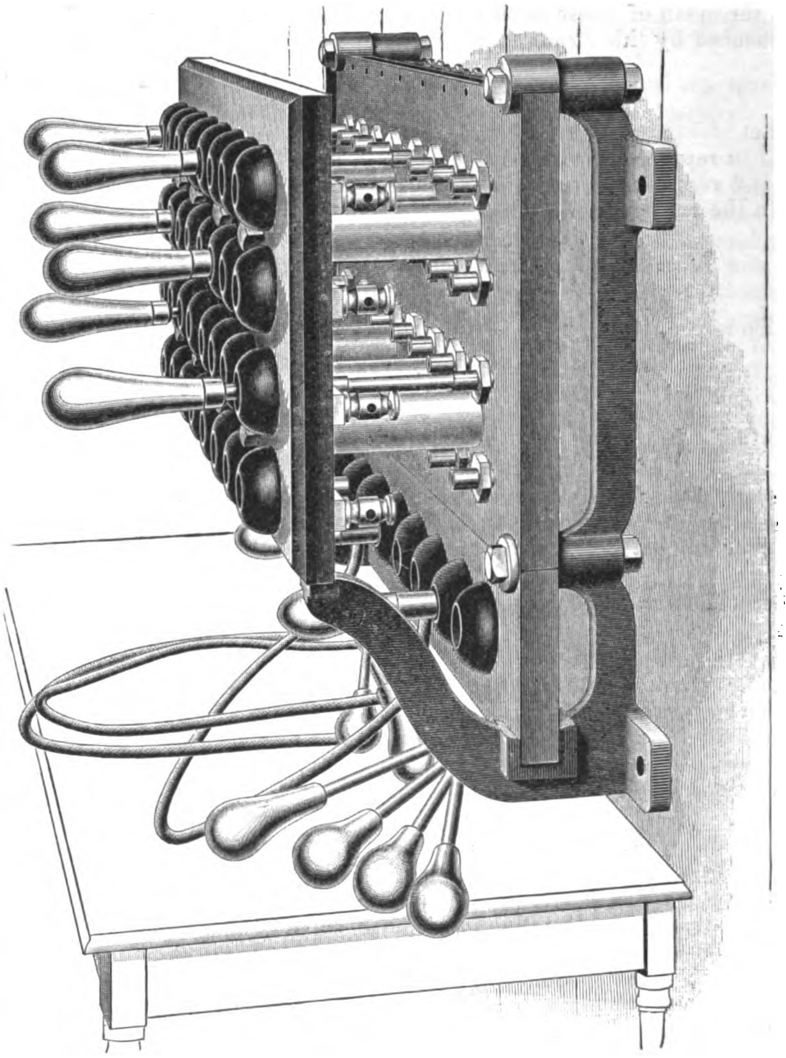

FIG. 1.

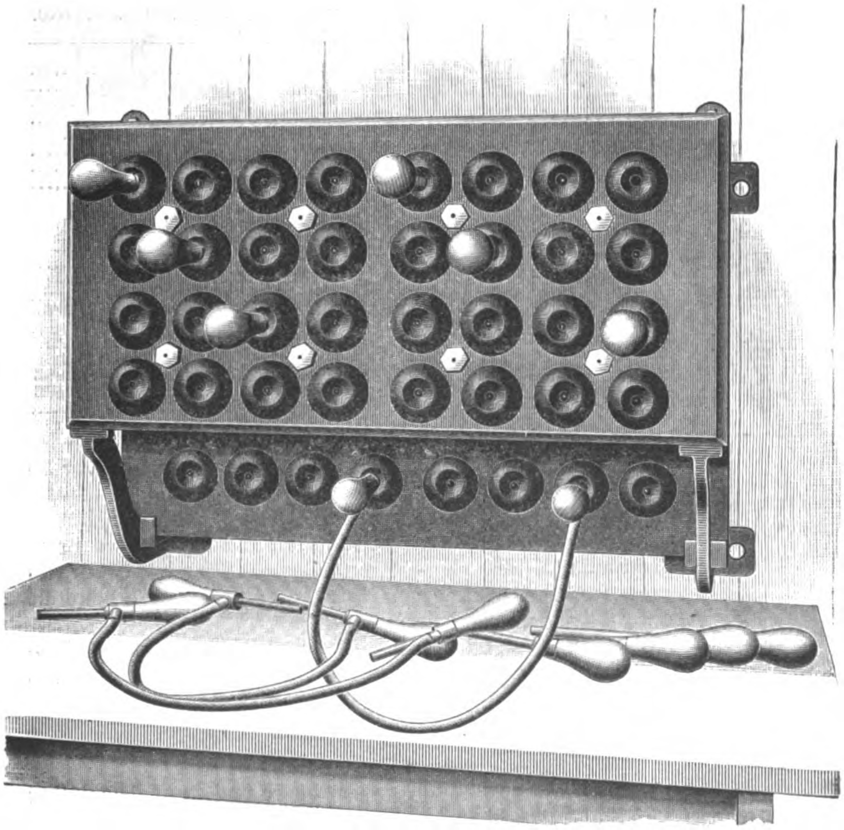

FIG. 2.

To transfer circuits from one dynamo to another when the machines are in operation without disturbing the lights, as for instance, transferring circuit No. 1 from dynamo No. 1 to dynamo No. 2. No. 1 dynamo is connected to No. 2 circuit by the plug, and No. 2 dynamo to No. 1 circuit. The circuit then can be broken between the dynamos and circuits No. 1 and No. 2, permitting No. 1 dynamo to be shut down, and the positive of circuit No. 2 connected to negative of circuit No. 1 by means of the transfer cables and plugs.

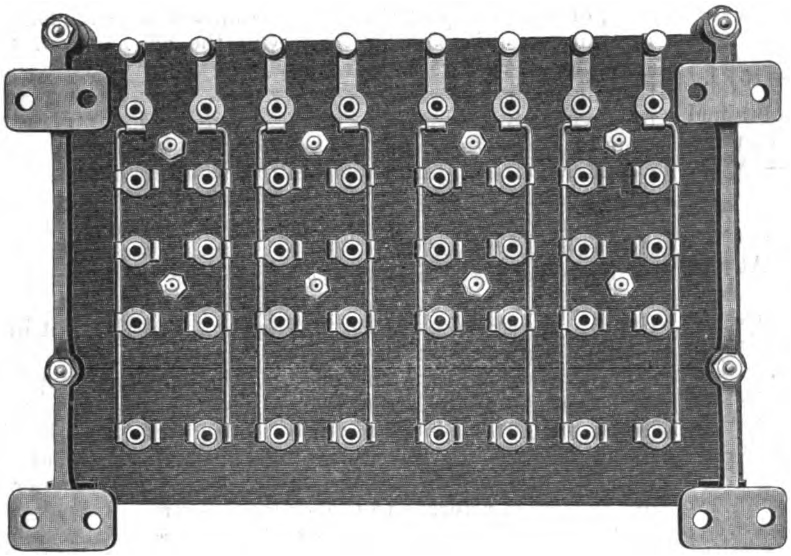

Fig. 3.

The wall space required for a four circuit board is 19x25 inches, and that for a six circuit board 24x35 inches.

ABSTRACTS AND EXTRACTS.

AN IMPROVED STANDARD CLARK CELL WITH LOW TEMPERATURE COEFFICIENT.[1]

BY H. S. CARHART.

The best form of Clark cell hitherto made is that of Lord Rayleigh, described in the Philosophical Transactions for 1885. The objections to this form are that the temperature coefficient is not the same for all cells, as is shown in Lord Rayleigh's paper, and it is so high as to introduce a very troublesome and uncertain error because of the difficulty of ascertaining the exact temperature of the cell; second, it is not so constructed mechanically as to prevent the mercury from coming into contact with the zinc when the cell is subjected to violent jars in transportation; thirdly, a great chemical defect is the facility with which local action takes place between the zinc and the mercury salt. I might add that the mercurous sulphate, purchased by Lord Rayleigh, evidently contained considerable salt in the mercuric form, as is shown by its turning yellow on mixing with the zinc sulphate solution.

All these difficulties I have, at least in large measure, overcome. Respecting the materials, the greatest care is required to secure and maintain cleanliness and purity in their preparation. The mercury must be distilled *in vacuo* after being cleaned by chemical means. The zinc sulphate should be free from iron as well as other impurities. The mercurous sulphate can be made almost or quite free from the mercuric form by using plenty of mercury; keeping the temperature down to the lowest point at which action will take place; and letting the mixture of salt, acid and metallic mercury stand for some time. I have made in this way a salt that remains white, not only when the free acid is all washed out, but when mixed with the standard zinc sulphate solution. Further, it remains white in the cell indefinitely if it is not exposed to a bright light.

Hitherto, the importance of the local action going on in a Clark cell appears not to have been appreciated. It accounts for some of the differences in temperature coefficient and leads to some more serious results in some cells. The zinc replaces mercury when in contact with the mercury salt. This amalgamates the zinc, producing a slight change in the E. M. F.; and then the amalgam is liable to creep up to the top of the zinc where it attacks the solder. The copper wire is thus sometimes loosened. The zinc sulphate follows up and the cell may thus be short-circuited by the zinc and the copper wire. Upon taking down one cell, which was perhaps a year old, I found that the zinc had been removed from the rod at the surface of the liquid and had been deposited again upon the rod at the surface of the mercury salt, in a solid frill around the zinc. The copper wire in this cell became entirely detached, partly because of the expansion upward of the marine glue, which brought a severe strain upon the wire.

The local action then increases zinc sulphate in the cell at the expense of the mercury sulphate and amalgamates the zinc rod. I have become convinced by some experiments extending over several weeks that this substitution process goes on only when the zinc is in contact with the solid mercury salt. The mercurous sulphate is only slightly soluble in a saturated solution of zinc sulphate. I prevent local action, therefore, by keeping the zinc and the mercury salt out of contact. The same device operates to raise the E. M. F. about 0.4 per cent. The following table exhibits the observed and calculated values of the E. M. F. of cells No. 17, 112, 113 in terms of No. 1 [old style] at 20° C.:—

[1] From the *American Journal of Science*, vol. xxxviii., November, 1889. London *Philosophical Magazine*, November, 1889.

Cell No. 1 was always very near 20° C., and the reduction to that temperature was made by means of Lord Rayleigh's reduction coefficient, .00077 per degree C.

The equation for the E. M. F., derived from the observations on No. 17, is

$$E' = E\,[1 - .000387\ (t - 15) + .0000005\ (t - 15)^2].$$

The calculated values for the three cells were all obtained by this formula. The change for one degree C. is, then, the following linear function of the temperature :—

$$-.000386 + .000001\ (t - 15).$$

The temperature coefficient ranges from .000401 at 0° C. to .000376 at 25° C., and to .000361 at 40° C. At the highest observed temperature in the preceding table it was only .000348. The curve of E. M. F. with temperatures as abscissas is clearly concave upward, indicating a fall in the temperature coefficient with rise of temperature. The change is, however, so small as to be quite negligible within the range of temperature to which a normal element is subjected in practice. Lord Rayleigh's cells show a change in the temperature coefficient directly the reverse of the above; that is, the coefficient increases by a very appreciable quantity with rise of temperature. For his No. [36] the coefficient ranged from .000556 at 0° C. to .00101 at 25° C., if his equation holds true for the higher temperature.

In making comparisons of E. M. F. I have used Lord Rayleigh's method, slightly modified, by means of which a difference of one ten-thousandth part is observed directly and with the greatest ease. In fact a difference of half that amount is easily measured. A comparison of half a dozen cells can be made in as many minutes without difficulty.

As to polarization, these cells show none with external resistance greater than 30,000 ohms. At 30,000 ohms the polarization is just discernible; and with 10,000 ohms it amounts to only one ten-thousandth part in five minutes. This fall in E. M. F. is less than the accidental differences between different cells in general, and much smaller than the almost unavoidable errors due to ignorance of the real temperature of the cell. If the cell is not closed on less than 10,000 ohms resistance, and only for a few minutes, the polarization may be entirely neglected.

As indicating the uniformity attained, the following relative values of the E. M. F. of six cells, only four days old, may be given:—9048, 9049, 9049, 9048, 9046, 9043. The last one was still approaching the others when last observed. Six cells of later construction gave the following relative values when less than two days old :—9182, 9182, 9182.5, 9182, 9182, 9182.5. The two sets of numbers do not represent at all the relative values of one set as compared with the other.

It will be seen from the table that Nos. 112 and 113 never differ by more than one part in ten thousand at the same temperature.

EFFICIENCY.[1]

BY PROFESSOR DE VOLSON WOOD.

THE term "efficiency" in mechanical science has become technical, and is restricted to a definite mathematical expression in the form of a ratio. When thus used its meaning is well understood, but its importance is increased by giving to it a broader definition, and a wider range of applications.

Efficiency is a result compared with the effort expended in producing that result.

This implies a division, and, therefore, may be expressed as a fraction, and, if it be abstract, a common unit must exist between the effort expended and the result obtained. If one be in thermal units, the other should be; if one be in pounds, or dollars, or feet, or time, or any particular quality or quantity, the other should be, respectively, the same. We will illustrate these principles by a few examples. Beginning with the familiar one of the steam engine we may have the following efficiencies :—If 10 per cent. of the energy of the steam admitted into an engine be transmuted into work, then will the efficiency of the steam, compared with the energy in it when admitted to the engine, be one-tenth or 10 per cent. If five per cent. of the energy of the steam in the boiler be lost by radiation, leaks, friction, etc., in passing from the boiler to the cylinder of the engine, then will the efficiency of the steam, compared with its energy in the boiler, be 0.10 × 0.95 = 0.095, or 9½ per cent. If the efficiency of the boiler be 0.70, that is, if the boiler utilizes 70 per cent. of the theoretical heat of the fuel, then will the efficiency of the system referred to the fuel be 0.095 × 0.70 = 0.0705, or more than seven per cent. If the fuel be coal, and the heat in it be one-fourth that in the plants from which it was produced, then would the efficiency of the system, compared with the heat in the plants from which coal has been produced, be 0.017625. If the heat energy in the plants be one per cent. of the energy received from the sun (and this is probably a *very* high allowance), then would the energy of the system referred to the original source of energy—that of the sun—be 0.0017625, or less than one-fifth of one per cent. We have referred to the sun as the original source, for we are ignorant as to *its* source of energy. Speculation is not agreed in regard to it; it may be the result of combustion, or of a shrinkage of volume, or the impact of external masses—or it may be an expenditure of original energy, and in these speculations it is generally assumed that the entire mechanical energy expended is entirely transmuted into heat, in which case the efficiency of such heat operation would be unity.

The efficiencies here given are less than unity, and it is always less than unity when the result is obtained from the source without an intermediate agency, deriving more or less power from another source. When the latter condition is involved, the efficiency may exceed unity. For instance, if money be carried, or deposited with another without being used, its efficiency could not exceed unity, and, although practically the efficiency may be unity, yet, considering friction, wear, tear and accidental losses, it is liable to be less than unity. If, however, the money be loaned and the borrower uses it in trade, commerce or agriculture, he may be able to pay for the use of it, and if he pay six per cent. periodically, the efficiency to the lender will be 106 per cent. If the borrower expended the money in raising a crop of wheat and received five times as much money for it as he expended, the efficiency would be 5—or 500 per cent. In this case the soil and other elements of nature constituted an intermediate agency which contributed to the result independently of the money expended in labor, seed, etc. If, however, the crop be referred to the wheat-producing capacity of the soil—that is, if the chemical elements of the wheat be compared with the corresponding chemical elements in the soil—the efficiency would be less than unity, and might be only a very small fraction.

The efficiency of a refrigerating plant is, by some, referred to the thermal units of work done on the fluid by the compressor, in which case the efficiency exceeds unity; for the compressor, in practice, adds only a small part of the heat that is removed by the refrigerator, the other part being absorbed by the circulating fluid from substances not affected by the compressor, and the latter measured by the work of the former. Even in this case, the efficiency may fall below unity when the result is compared with the energy expended in operating the compressor.

Negative efficiencies are ideal, and are not reported in practical operations. Since all efforts, all work, all heat, all energy, are positive when considered by themselves, negative efficiencies exist only in the *sense* in which one effort is considered in reference to another. Thus, steam in an engine does work, but air admitted to a compressor does no work, but work is done upon it. In the sense of the fluid in a compressor doing work, the efficiency is strictly zero, and in the sense of *its* doing work when driven, it is negative. Again, if a man promised to pay five bushels of wheat for the use of a wheat field and the crop were an entire failure, the efficiency of the crop would be zero, and if he delivered the five bushels according to agreement, he would necessarily secure it from some other source, and the efficiency of the transaction would be negative.

---

[1] From *The Stevens Indicator*, October, 1889.

As for an *imaginary* efficiency it has too often proved a *reality* to *visionary* dealers.

It is unnecessary to illustrate further, and we will simply mention a few other subjects to which it is, or may be, applied. The efficiency of a beam is the ratio of the load it carries to that required to break it, and is the same as the factor of safety. We have the efficiency of riveting—of belt transmission—of the flow of fluids through orifices and pipes—of a bank—of an instructor—of a student—of an institution of learning—of a journal—of an official, etc. Many of the latter cannot be expressed mathematically, for the quantities do not admit of exact measurement. While it may be said that one man is more efficient than another, yet if it be said that he is twice as efficient, it will be considered as a matter of judgment, and not the result of measured quantities.

RULES FOR ISOLATED LIGHTING PLANTS.

MR. EDWARD ATKINSON, President of the Boston Manufacturers' Mutual Fire Insurance Company, issues a special circular, as follows:—

HAZARD FROM OUTSIDE ELECTRIC CURRENTS.

Electric lighting was first introduced in a very few risks insured by this company before the year 1881; in that year and in the first six months of 1882 it was adopted in a very considerable measure. In this period of its early introduction, prior to the 1st of April, 1882, we received notice of 23 fires which had been set by the electric current in only 61 mills which had then been equipped. No claim for loss was made on any of these fires, but they disclosed conditions which were very alarming to us. An immediate investigation was made, under the direction of Mr. C. J. H. Woodbury, and certain rules were adopted for putting up the apparatus, insulating the wires, and guarding against the dangers disclosed in these 23 fires. These rules were immediately submitted to all the electric light companies or manufacturers of electric lighting apparatus who had any standing in the community, and were at once adopted by them as well as by all insurance companies. They have not been changed since that date, except so far as new inventions have called for modifications.

Since April 1, 1882, a period of nearly eight years, we have received no notice of any fire which could be attributed to electricity in any risk insured by this company, and, of course, no claim has been made upon us for a loss which could be attributed to this cause. Our experience, therefore, justifies the conclusion to which we came after the first two years of electric lighting, that, under proper safeguards, it is the safest method of lighting that can be introduced. Electricity has also been applied in some of the works insured by us as a motive power, and electricity is now applied to lighting or motive power in over 600 risks which are insured by the Factory Mutual Companies.

Attention, however, has lately been called to the danger of wild currents of electricity generated on the wires which may be in use for lighting, for power, and for the railway service in many cities. There appears to be very little doubt that the recent destructive fire in Boston originated in the diversion of a high tension current of electricity from its own wire to an electric clock wire, on which it was carried to the building in which the fire originated. There appears to be little doubt that this conflagration may be attributed to the lack of precaution in guarding against an outside current of electricity. Such currents may be carried from their proper wires to other points in all cities or towns in which electric light or power is widely distributed on the public streets or over private buildings.

In order to guard against this hazard, the owners and managers of mills and works insured are advised to establish the following rules for the protection of their premises. These rules, after having been drawn by us, have been submitted to experts in various branches of electric science, who are of the highest authority. The forms have been modified by them, again considered on our own part, and are believed to be suitable for what may be called an emergency.

RULES FOR GUARDING INSURED PROPERTY AGAINST THE HAZARD OF STRAY CURRENTS OF ELECTRICITY GENERATED OUTSIDE OF MILL YARDS.

1st. No foreign wires of any kind shall be attached to buildings insured by this company, for the purpose of carrying electric currents across the yard to any point.

2d. All electric wires which may be required by the insured shall enter the premises at one point near the head-quarters of the night watchman, where they can be kept under supervision; each of said wires shall be guarded by a protector against strong currents, operating by opening the circuit, and by a lightning arrester.

3d. Such protectors against strong currents shall be located in a dry, accessible place inside the building, and as near the point of entrance of wires as possible, and shall be without ground connection; such protectors shall be mounted on non-combustible and insulated supports, which shall be provided with a receptacle for the burning or melted parts of such apparatus.

4th. The lightning arresters on all wires must be placed between the protector against strong currents and the electrical portion of the apparatus within the building to which such wires are connected. No ground wires for such lightning arrester shall be attached to gas pipes within the premises of the insured.

5th. All electric wires which may enter the premises of the insured must be insulated, between the line wire on the insulator attached to the buildings outside and the protecting device within, with the best quality of waterproof insulation. Moreover, such wires must enter at a distance of not less than three (3) inches from any other wire or any conducting material.

6th. If any wires carrying high tension or strong currents are to be carried over or under other wires on the property of the insured, they shall be attached to poles so near to each other, with one wire so far above the other, that, if a break should occur, the pendent wire between these poles may not be long enough to come in contact with the wire below, or, if not carried on poles, these wires shall be so placed or protected with guard wires as to render a contact between different wires impossible.

7th. If the high and low tension systems are in use in the same yard, even when developed within the works, the wires must be kept separate, and so wide apart that no contact or cross arc can be made.

If any changes are to be made on which any advice is required, in order to establish the safeguard herein recommended, an inspection can be made.

KEARNEY, NEBRASKA—ITS PROSPERITY.

THE City of Kearney, Nebraska, is just half-way between Boston and San Francisco, being 1,733 miles from each of those cities. It is probably a surprise to many residents of New England to learn that the population of Nebraska is greater than that of Connecticut and Rhode Island combined, and nearly equal to that of Massachusetts. Kearney—the midway city—with a present population of more than 10,000, is in its growth and enterprise one of the most typical of western towns. Only a few years ago the Chicago, Burlington and Quincy railroad managers thought it would be folly to build further west than Lincoln, but now Kearney has two railroads at its doors, four from 40 to 100 miles distant, and half-a-dozen more reaching out towards it as rapidly as possible. The business men of the city reach out for nothing short of a large slice of the general business of the Northwest, and they seem to be getting generous bites off it already. The town is of special interest to the electrical fraternity, as being the head-quarters of the Western Enginering Co., electrical engineers and contractors, established at first some two years ago at Lincoln, by Mr. D. C. Jackson and Mr. J. G. White, soon after their graduation from Cornell University. Readers of THE ELECTRICAL ENGINEER are familiar with the names and work of both these gentlemen, and will be glad to learn of the prosperity that has attended their bold push to the west, where they carried their knowledge and trained abilities in the interest of electric arts and their own fortunes.

.... WORDS, we know, though but wise men's counters, are the money of fools.—*S. P. Langley.*

.... I WAS the first to show that sheets of paper could be made to insulate, so as to be available for the construction of condensers. I originated the idea of constructing artificial submarine circuits, and suggested their use as a means of solving by direct experiment the problems connected with submarine telegraphy.—*S. Alfred Varley.*

.... I KNOW of nothing which requires a more general exact knowledge of the mechanical, electrical and other properties of materials, and the strength and stiffness of structures which may be subjected to local heating, than the design of the armature of a dynamo.—*John Perry.*

CORRESPONDENCE.

NEW YORK AND VICINITY.

No Electric Lights in Roman Catholic Churches.—Mr. Edison and the Grand Jury.—The Electric Lighting Companies Preparing to Sue the City for Damages.—Subway Explosions.—Mr. Edison's Kind Attention to Some Bright Boys.—Electric Welding Adopted by the Bishop Gutta Percha Co. and the J. A. Roebling's Sons Co.—Prompt Restoration of Full Service by the Edison Company after Destruction by Fire of its Down-town Station; the Proposed New Station.—The New Building of the Edison General Electric Co.—Ex-Mayor Hewitt on the Subway Commissioners.—Resignation of Commissioner Gibbens.—Darkness and Disasters.—The Delany Line Adjuster Used at the Jersey City Office of the Erie Railway.

ONE of the few churches in the country which has adopted the electric light is that of the Holy Innocents in this city. It is to be dispensed with hereafter, however, the Sacred College of the Propaganda in Rome, after mature deliberation, having decided that electricity should not be used for the illumination of sacred edifices.

Mr. Edison appeared before the Grand Jury in this city in December, and, although all hearings before that body are conducted with every possible precaution against publicity, it is reported that the distinguished inventor suggested that a law be enacted prohibiting the use of electric currents of such a character as to be dangerous to life.

When the work of destroying electrical property by the city authorities finally ceases, the various electrical companies will proceed to write up their books with a view to bringing suit against the City of New York for damages incurred, which will make a pretty large bill. It is said that the amount to be sued for by the East River Electric Light Co. alone will exceed $250,000, and it is safe to say the total will exceed $1,000,000.

It is over a year since the first serious gas explosions occurred in the electrical subways, and it was supposed that steps had been taken to prevent them; for there is no question that they are a menace to human life, which with the extension of the subways will, of course, be greatly increased. There have been two explosions within a month, one of which, at the corner of Fourteenth street and Sixth avenue, made a total wreck of the man-hole. Those which have occurred heretofore have not caused sufficient damage to require much time for repair, but in this case passers by had an opportunity for two days to witness the powerful explosive effects of the accumulated gas which seems to pervade the entire subway system.

The doll industry at the Edison phonograph works in Orange, N. J., is said to be in a flourishing condition, the factory being well stocked with parts of dolls which will be put together at once. A delivery of fifty dolls was made on January 3d, and it is thought that within a month there will be an ample supply placed on the market.

The Huyler candy factory, corner of Eighteenth street and Irving place, has been fitted out with electric motors for its machinery, which is distributed through six floors. A saving of 25 per cent. in the coal bill of the establishment has been guaranteed.

Two city boys have recently completed a miniature launch which they have placed in commission on the yachting lake in Central Park. It was christened the "Edison," and is operated by a bichromate battery. They were so well pleased with its success that they wrote a letter to Mr. Edison containing a description of the craft. In his reply to the boys' letter Mr. Edison highly complimented their work, and at the same time suggested a more suitable battery, kindly giving detailed instructions as to its arrangement.

The Bishop Gutta Percha Co., of this city, and the John A. Roebling's Sons Co., of Trenton, have adopted electric welding in their respective factories for the joining of the ends of wire. This process appears to be admirably adapted for the purpose, and will no doubt be gradually introduced into all similar establishments.

The Edison electric light station at 255-7 Pearl street, which was completely burned out by fire January 2d, has been refitted and was again in full operation in a fortnight. Meanwhile the auxiliary station of 5,000 lamps capacity, on Liberty street, has been kept in continual service. The Pearl street station will be used until the completion of a new down-town station, which will be located just above the approach to the East River bridge. The construction of this station will begin next spring, and it is expected that it will be finished during the year.

The Edison General Electric Co. has filed plans for the construction of an office building at Nos. 42 and 44 Broad street, running through to Nos. 38 and 40 New street. It will be ten stories high, 41 feet front and 143 feet deep, and will cost $250,000.

Ex-Mayor Hewitt, in commenting on his attitude towards the electric wires during his administration, says that he never saw such appalling ignorance as was displayed on the subject by Messrs. Moss, Hess and Gibbens. He admitted that he was ignorant; but said, "they did not know enough to know that they knew nothing of the subject."

Mr. Gibbens has recently resigned from the board of electrical control. Various reasons are assigned for his action, but it is believed to be due to the adverse criticism of the press. It is also thought that he may be a candidate for a position on the new state board, the salary for which will be $3,000 in excess of what he has heretofore received. It is stated that his successor will be an electrical man.

Since the suspension of arc lighting on the river fronts, two men have plunged into the East River, while under the supposition that the lights on the Brooklyn side were at the boundaries of New York city. The police have restrained several pedestrians from attempting to walk over on the water, in spite of the fact that the fare on the bridge is only one cent.

The New York, Lake Erie & Western R. R. Co. has just placed in use at the Jersey City telegraph office the Delany adjuster, recently introduced to insure a working adjustment of instruments in all kinds of weather.

NEW YORK, January 23, 1890.

PHILADELPHIA.

Councils Still Considering a Municipal Electric Lighting Plant.—The Lighting Contracts for Another Year.—A New Gas and Electric Fixture Company.—Overhead Wires in Camden, N. J.—Prosperity of the Bell Telephone Co. of Philadelphia.—Complaints that Arc Lights are Not Up to Candle Power Required.—The City Will Try to Devise and Enforce a System of Tests for Next Year.

BOTH branches of city councils concurred in a resolution presented by Mr. M. C. Smith, requesting the joint special committee of the two chambers, appointed to consider the advisability of establishing an electric light plant for the city, to report early in January, giving a detailed statement of the cost of construction of such a plant and the cost of maintenance.

Mr. Smith stated that a plant of 1,200 lamps could be constructed at a cost of $300,000, and that $90,000 would be required each year to maintain it. This plant would do away with nearly 3,000 gas lamps.

Representatives of the various electric lighting companies in Philadelphia were in conference recently with Superintendent Walker and Director Wagner, concerning the terms under which contracts for electric lighting will be made next year. It was determined that bids shall be made according to amperage and voltage, the proposals setting forth the amount of the current to be furnished and the voltage of each lamp. Each circuit will be provided with a test station, so that city employés can ascertain at any time the strength of the currents passing over the wires. The standard required of the lamps will be 1,000 c. p.

Recent tests have shown that the city lamps lose 27 per cent. of their brilliancy by reason of dirty globes. Next year the globes will be one-quarter frosted.

Articles of incorporation have been filed in Camden, N. J., by the National Gas and Electric Fixture Co., with a capital stock of $500,000, $25,000 paid in. The incorporators include capitalists from this city, New York and New Jersey. Among the Philadelphians interested are Clement M. Biddle, William N. Yeaton and Benjamin Thackara. In reference to the new company one of the latter said yesterday:—"We intend to do a buying and selling business on a large scale. At present we are negotiating for a large plant in Camden. Should we fail to get this plant we will build one of our own."

The rapid increase of electric light wires in Camden has caused the linemen of the South Jersey Telephone Co. to protest against the dangerous proximity of the two sets of wires. They have had several narrow escapes from the contact of wires recently. Superintendent C. A. Janke protested, and the fire commission passed a resolution forbidding the electric light company the use of the telephone company's poles, except under the latter's supervision.

The annual report of the Bell Telephone Co., of this city, for 1889, shows the cost of its lines and equipment to be $610,410.94 of which $142,615.14 was paid out in underground construction. The expenses for the year were $233,630.08, and the receipts, $434,191.97. The company had invested in real estate, $59,924.53, and $236,046.79 in stocks, bonds and other securities. Its entire assets aggregated $1,000,565.52. The amount paid in dividends was $67,200.

Citizens of the Eighth Ward have called attention to the poor quality of the electric light furnished. Chief Walker, of the electrical bureau, said that his department had been making tests, and that a report would be completed showing the result of the measurements. In the specifications for 1890 submitted by Director Wagner, this matter of inferior candle-power will be thoroughly covered. The electric companies will be required to state the candle-power they propose to furnish, and also to agree upon a system of measurements which shall be used in arriving at the quality of their light. These measurements, Mr. Walker said, would give the necessary candle-power. The measurements that the bureau have been making have been very tedious. Ever since last June, a period of nearly seven months, the work has been going on, and mostly after 12 o'clock at night, when the streets are deserted.

Mr. Graham, of city council, said that he had been informed by Director Wagner that next year he would insist that the electrical companies should be paid for their lamps in proportion to the candle-power furnished.

Chief Walker said that there was no such thing as a light of 2,000 c. p. When the Brush company contracts for a light of that power, they always insert in parenthesis the word "nominal."

PHILADELPHIA, January 16, 1890.

BOSTON.

The Cause of the Recent Great Fire not yet Ascertained; Corrected Statement of the Losses.—Experiments Before the Aldermen.—Excitement Over the New City Lighting Contracts.—Citizens and Insurance Men Protest against Duplicating the Present Overhead System of Wires.—The Attitude of the Boston Electric Light Company.—Lectures by Mr. Geo. W. Mansfield.—The New England Electric Exchange.—Output of Telephones.—Electrical Door Openers at the Tremont Theatre.—The Police Signal System.

THE question of the origin of the fire which occurred on Thanksgiving Day has not yet been settled, evidence still being taken. Two weeks will probably elapse before the issue of the report by the fire marshal.

Mr. John C. Paige, a prominent insurance man of this city has made a complete compilation of the losses by the fire. It shows that the loss on real and personal property amounts to $3,784,871, and the loss of the insurance companies to $3,164,836.

The first estimates were based upon the average stock carried by the firms losing, but upon later investigation it appears that the fire occurred between seasons, as it were, when the change in stock was in progress, and develops the fact that most of the firms had but a small stock on hand, hence the loss was not so heavy as the first estimate would indicate.

Some experiments have been tried recently before aldermanic committees to show some of the results of very heavy currents upon telephone instruments and "fuses;" the recent fire bringing forward many contrivances for guarding persons and property from danger. A wire was attached to the dynamo of an arc circuit of the Boston Electric Lighting Co., carrying 46 lights, the voltage being 2,300. A telephone was put into the circuit and the entire current sent through the instrument with the purpose in view of ascertaining whether the telephone could be set on fire in that way. At first smoke was emitted from the box, soon subsiding, however. When the box was opened it was found that the silk covering upon the wire surrounding the coil had been burned off, causing the smoke, and that the wire had melted. The regulator upon the dynamo responding automatically to this condition so reduced the pressure that all danger from that source ceased. The box was not inflamed, nor even charred.

A test was also made of several fuses such as are used by the telephone company.

The test was so successful that whenever the current under 2,300 volts pressure was sent into the wire supplied with a fuse the latter melted at once, thus breaking the current. There had been some expectation that an arc might be formed between the severed ends, thereby renewing the danger, but it was not realized.

The results of these tests raised a strong presumption that electricity was not the cause of the big fire.

The streets are full of talk regarding Mayor Hart's recent action in awarding the contract for the city's electric lights to another company than the Boston Electric Light Co., which has lighted the city for the past half dozen years.

This action will, if carried through, necessitate the erection of a duplicate set of poles and wires; and many petitions of remonstrance have been received at City Hall against this multiplication of the sources of danger already too plentiful.

Mayor Hart recently took a trip through the large cities of the country with a view to ascertaining the ideas of city officials with regard to the overhead wire question, and also to find out the cost of lighting the streets.

Boston has paid 65 cents per night per light for her arc lights, and the mayor considers this price to be exorbitant, finding that none of the cities visited pay over 50 cents. As the contract with the present company expires this year the proposals for lighting were sent in, no proposal over 40 cents to be considered.

The Boston Electric Light Co. made no tender, claiming that they could not light the 800 lights in the city at that rate. In consequence, the contract was awarded to the Suburban Electric Light and Power Co., with the understanding that everything shall be ready in sixteen weeks, at the rate of $39\frac{74}{100}$ cents for Boston, $37\frac{22}{100}$ for Roxbury and 40 cents for Charlestown. The company have expressed their willingness to put the wires underground. While the preparations are being made, however, the Boston Electric Light Co. will supply the lights at the same rate as before.

President Gilbert, of the Boston Electric Light Co., says that the directors of the company will do all in their power to protect the interests of the stockholders.

He had been willing to leave the settlement of a contract price to the decision of the gas commissioners or would consent to an inspection of the company's books by experts provided by the mayor, and abide by the result. If Mayor Hart had removed the restriction of a 40 cent limit he could have put in a bid of 50 cents for certain districts and of a lower rate for other districts, which would have brought the average expense below 50 cents a light per night. It costs the company, he says, 47 cents per light to light the streets of Boston at present.

Insurance men are protesting against the duplication of electric wires, and a petition has been presented to the mayor and aldermen to that effect. They state that they do not want to stand in the way of progress, but they do protest against the construction of four or five hundred miles of wires, carrying a voltage as great as that which has recently caused such a furore in New York, over the streets of the city, merely to save a comparatively small annual sum per year.

Many people have applauded Mayor Hart for his economy; but they do not consider the fact that to save a few thousands they are endangering many millions of dollars worth of valuable property. Both insurance men and property owners are desirous of making the hazard as small as possible, and hence the protest, which reads as follows:—

BOSTON, January 10, 1890.

To His Honor the Mayor and the Board of Aldermen of the City of Boston:

GENTLEMEN:—The undersigned fire underwriters doing business in this city respectfully represent that while it is evident that electricity is to be generally used for light and power, this use is, in the present state of the science, attended with dangers, especially with wires carrying a current of high tension.

It is therefore desirable, for the safety of life and property, that there should be no unnecessary duplication of wires, as this implies an increase of the dangers incident to their use.

For this reason the undersigned feel called upon to protest against the introduction into this city of another electric company running its wires throughout the streets and over the tops of our buildings, as they believe that the slight saving in money which the city would effect by having its streets lighted by this new company would in no way counterbalance the risk which would be run by these added and unnecessary elements of danger.

If it should be decided, in spite of this protest, to allow another electric light company to carry its wires through our streets, it is the hope of your petitioners that it shall be a condition in the contract that the wires put up shall be insulated in the most approved manner, and in other ways arranged to guard against accidents.

The petition is signed by all of the prominent insurance firms in the city,

There have been a good many lectures in this vicinity of late on electrical subjects. Mr. G. W. Mansfield, electrician of the Thomson-Houston Co., gave an interesting one on the 26th, on the subject of "Electrical Railroading."

Early in January Mr. Mansfield lectured upon the use of the electric current as a motive power.

These lectures by Mr. Mansfield are exceedingly interesting and instructive. It is an excellent plan to place before the public the correct theory and practice of these electrical applications, thus tending to set aside (in a great measure) the silly fear, born of ignorance, with regard to electric cars. There are people in this city to-day who will wait a quarter of an hour to take a horse car, rather than get "shocked" in the electric one.

The quarterly meeting of the New England Electric Exchange was held on January 13th in the rooms of the Boston Electric Club, President Alexander in the chair. The matter discussed at greatest length was that of providing examiners of applicants for licenses.

Mr. Frank Ridlon, for the committee on examiners, reported that it was no easy matter to procure examiners, and said the only thing to be done was to hire competent experts and create a board of two with the possibility of calling in a third.

This caused a long discussion, resulting in the passage of two votes. The first to continue the committee with instructions to report to the executive committee the best way to obtain a permanent examiner. The second vote empowered the board of directors to take such action as it may deem proper to secure an examiner.

Mr. Spalding reported that the committee on instruction had made no progress on account of lack of time. Mr. Ridlon said that his idea was to print a set of rules for circulation amongst teamsters and policemen, setting forth the proper course of action in case they should meet with broken wires.

The statement of the output of telephones by the American Bell company for the month and year ended December 21, with comparisons, is as follows:—

	1889.	1888.		
December:—				
Gross	5,010	3,948	Inc.	1,062
Returned	2.140	2,163	Dec.	23
Net	2,870	1,785	Inc.	1,085
Year:—				
Gross	57,167	53,609	Inc.	3,558
Returned	24,967	23,601	Inc.	1,366
Net	32,200	30,008	Inc.	2,192

The electric doors of the Tremont Theatre are now in readiness for use. No other theatre in this or any other country (except the Broadway, New York) has such a safeguard and convenience. By simply touching a button in any of eight handy places in the theatre, seventeen sets of folding doors to as many exits fly open immediately. The expense attending the furnishing of these doors is a hundred times repaid by the safety felt by the theatre's patrons.

The number of police signal boxes in Boston now is 411; miles of wire, 213.5; average cost per mile, $99.10. There are in the service 9 wagons and 19 horses, with one wagon and two horses in the repair department. During the year the wagons made 23,621 runs, covering 15,089 miles; 24,374 prisoners and 780 lost children were taken to the station house, and 692 injured and insane persons to the station house or elsewhere.

BOSTON, January 18, 1889.

CHICAGO.

The Chicago Electric Club to Entertain Eastern Delegates to the Electric Light Convention on Their Way to Kansas City.—Overhead Wire Privileges.—The Illinois Electric Light Association Organized.—A Suit Touching the Rights and Privileges of Telegraph Employes.—A Thomson-Houston Electric Motor Rescues a Printing Office from Serious Loss.—Electric Club Notes.—The Chicago Telephone Co. and the City Departments.—New Incorporations.—Personal Notes.--Suspension of Telegraph Service and Board of Trade Operations by the Storm of January 12.--Edison Isolated Plants of Large Size.

THE Chicago Electric Club proposes to entertain the eastern delegates to the Kansas City Convention of the National Electric Light Association, *en route* on the "electric limited," February 10. The board of managers instructed W. A. Kreidler, secretary of the club, to extend the invitation, which has been accepted by Secretary Garratt, of the Electric Light Association. The Chicago Electric Club has appointed the following committee of arrangements for the entertainment of its guests:—W. A. Kreidler, chairman; F. E. Degenhardt, Alex. Kempt, F. G. Beach and F. B. Badt.

The question of overhead wires is vexing Chicago. Before the annexation of several suburban towns and cities last spring, the local authorities had passed ordinances giving to several companies the right to string overhead wires. These franchises, though accepted, had not been utilized when the suburbs concerned were annexed. It is now the fixed policy of the Chicago authorities to refuse permission to any company to put up aerial circuits. A few weeks ago the Lake View Electric Light Co. decided to avail itself of its franchise, and, therefore, applied to Commissioner Purdy to issue a permit, enabling it to commence work. He refused at first, and referred the matter to the legal department of the city. A decision was given, stating that the ordinance was valid, inasmuch as the Supreme Court had held that annexation did not affect ordinances granted by municipalities before the incorporation of annexed districts. The commissioner thereupon issued the permit. The case is interesting, as several companies held similar franchises, granted by Hyde Park and the Town of Lake, before they were annexed. The companies which hold these franchises maintain that it would be exceedingly unjust if their franchises were made null and void, simply because the towns in which they secured privileges have been swallowed up by a larger municipality. In behalf of companies which have been operating in Chicago it is said, on the other hand, that it seems exceedingly unjust to allow a new company to string overhead wires while such a privilege is rigidly withheld from them. Professor Barrett, the city electrician, is firmly opposed to overhead wires anywhere within the city limits.

Representatives of Illinois central station companies met at the rooms of the Chicago Electric Club, January 18, and organized the Illinois Electric Lighting Association. Mr. Allen R. Foote, chairman of the Committee on State and Municipal Legislation of the National Electric Light Association, summarized the benefits to be derived from the organization of a state association. He said this was the seventh state organization formed under the plan of the National Electric Light Association. The following temporary officers were elected:—President, C. H. Wilmerding, Chicago; first vice-president, A. L. Ide, Springfield; second vice-president, Douglas Hopeman, Ottawa; secretary and treasurer, Charles E. Gregory, Chicago; executive committee, Charles I. Page, Englewood, and M. B. Beal, Rockford.

During the early part of January, Mr. Frederick H. Tubbs, superintendent of the Western Union Chicago office, appeared before Judge Tuthill in response to a citation, requiring him to show why he should not answer questions asked by a commissioner appointed by a Kansas City court to take take testimony in a suit of Edward L. Randall against the Chicago, Rock Island & Pacific Railroad Co. The suit is one that has a particular interest to telegraph operators, and has been pending for some time. The plaintiff seeks to secure $25,000 damages. He was a telegraph operator for the company at Davenport, Ia., but was discharged in 1886, because, as he alleges, he was active in organizing a branch of the Order of Railway Telegraph Operators. After his discharge, it is alleged, he was "black-listed," and a secret circular was sent out stating the fact. When Randall came to Chicago he was refused work in consequence, as he asserts, of the circular. Mr. Tubbs was summoned before the commissioner appointed to take testimony in Chicago, and was asked questions concerning the circular. To several of these queries he refused to reply. He was then summoned to show cause why he should not give answers. Judge Tuthill decided that Mr. Tubbs must reply. He thought the rule of privileged communications could not hold in this case. Randall was not an employé of the Western Union, and it was stretching the rule a great deal, the court thought, to say it applied because Randall might become an employé of the company at some time.

Early in January a boiler in the basement of the building occupied by the John Morris Printing Co., Chicago, exploded. Several persons were seriously hurt and one employé was killed. The owners of the printing office anticipated a serious loss from the stoppage of work caused by the wreck of their steam plant. A 40 h. p. Thomson-Houston electric motor was installed and connected to the Edison circuit. The explosion occurred on Friday, but, as a result of the employment of the electric motor, the printing company was able to run its plant as usual on the following Monday.

At the meeting of the Chicago Electric Club, January 6, Professor Louis Bell read a paper on "The Theory of Compounding Dynamos for Constant Potential." At the club meeting, January 20, Mr. Foree Bain read an interesting paper on "Experience as a Teacher in Electrical Engineering." The writer of the paper described a number of simple but ingenious means which he had devised for accomplishing practical electrical results. His lecture was fully illustrated, and was extremely interesting and practical.

The Chicago Telephone Co. has removed its telephones from the city building and the police stations throughout the city. When the city council passed an ordinance taxing the company, it felt that it was relieved by that act from furnishing free telephone service to the city. The council will probably make an appropriation for telephones.

Belvidere, Ill., is to have an electric light plant. The central station will be equipped with Westinghouse alternating dynamos, with a capacity of 750 lights.

The Naperville, Ill., Electric Light Co. has been incorporated with a capital stock of $12,000.

The Minonk, Ill., Electric Light and Power Co. has been incorporated with a capital stock of $15,000, by M. L. Newell, A. B. Knipp and G. W. Weber.

The Macomb Electric Light and Gas Co., of Macomb, Ill., has been formed with a capital stock of $25,000. The incorporators are Charles Ketteron, H. W. Cummings and J. N. Rume.

Mr. F. G. Beach, president of the Chicago Electric Club, was seriously ill early in the month, but has now entirely recovered.

Mr. Allen R. Foote, who has charge of the department of electricity for the eleventh census, was in Chicago January 20.

Mr. H. Ward Leonard, of the United Edison Co., New York, attended the meeting of the Chicago Electric Club, January 20.

The Board of Trade practically suspended operations on January 13, as the storm of the preceding evening had worked havoc with all wires entering the city.

The Chicago Edison Co. recently installed an incandescent plant in the Windsor Theatre in Chicago. The house is wired for 900 lights. The plant consists of two Edison compound dynamos and a 90 h. p. Russell engine. The Edison company has also installed a 250-light plant at the salesrooms of Lyon, Potter & Co.

CHICAGO, January 22, 1890.

ST. LOUIS.

The Public Lighting; the System Partially Started January 1.—Telephone Service Disturbed.—Consolidation and Reorganization of Lighting and Power Companies.—The Western Union Telegraph Office Burned Out.—Great Damage to Electric Wires from the Sleet Storm of January 6-7 and the Cyclone of January 12.; Prompt Restoration of Service.--Electric Traction.--Corporation Notes.—A New Gas Scheme.

ST. LOUIS being the first city to undertake a complete illumination of streets, alleys, parks and city buildings by electric lights, its progress is no doubt watched with interest by other cities as well as by the electrical trade interests. The Municipal Electric Light and Power Co. were not prepared to begin their part of the service January 1. The Missouri Electric Light and Power Co. and the Laclede Gas Co., contractors for the incandescent lighting of the alleys, parks and city buildings were ready, and at 8 o'clock P. M., December 31st, the lights were formally turned on by the daughter of Mayor Noonan.

So far as the lights are concerned everything is successful. The alley lighting is especially satisfactory to every one, and particularly so to the police authorities. But so far as the telephone service is concerned the matter is not so satisfactory. In the southern part of the city, the territory covered by the Missouri Electric Light and Power Co., the telephone service was almost annihilated by induction from their Westinghouse alternating currents. Trial runs some days previous had indicated this result. The Bell Telephone Co. would not put up with the disturbance, and threatened an injunction. The electric light company claimed that the trouble was caused in some way by "dead" wires; while the telephone company claim that the induction is due to an unbalanced condition on the two parallel electric light main conductors. The mayor ordered both companies to discontinue their lights until the disturbance could be abated. The supervisor of city lighting was instructed to remove all "dead" wires. The electric lighting companies voluntarily aided in this work, furnishing men and teams. In the northern part of the city—the Laclede Gas Co. territory—this clearing out of "dead" wires was followed by such a diminution of the disturbance that in a few days the service of the electric lights was permitted to be resumed. But in the Missouri company's territory the situation was but slightly improved, and they are now adjusting their circuits so as to produce a better balance of the outgoing and incoming circuits. The rules of the board of public improvements covering this case are as follows:—"The two electric light wires of each metallic circuit shall occupy the same cross-arm on each pole, and shall run parallel to each other not more than one foot apart along the entire route of the circuit." It seems that the Missouri company have not fully executed the provisions of this rule, at least the telephone company so claim.

Aside from the telephone troubles there were a few cases of persons being slightly shocked by coming in contact with "dead" wires. The state of the weather was very unfavorable. During the first week of the month there prevailed an almost continuous slow rain, which finally terminated in a heavy sleet storm. Under these circumstances and the fact that much of the wire construction had been unduly hurried, and in some cases left in an unfinished state, it is not surprising that some slight mishap should occur.

The mayor has ordered the supervisor of city lighting to enforce the proper erection of all private wires and the removal of all wires as soon as they become useless.

A joint committee of the two branches of the city legislature has been appointed with authority to investigate the "dead" wire question. With these investigations and proper precautions a satisfactory solution of all trouble is confidently expected.

On December 30th, 1889, the St. Louis Illuminating Co. increased their capital stock from $100,000 to $500,000. They have absorbed the United Electric Light and Power Co. on the following basis:—paying in bonds $326,000 to the United Electric Light and Power Co., $125,000 to the St. Louis Illuminating Co., while the balance, $49,000 will be held in the treasury. The reorganization of the St. Louis Illuminating Co. was effected on January 4, 1890, and resulted as follows:—Jas. Campbell, president; J. D. Thompson, vice-president; C. S. Horton, secretary and treasurer; directors, Jas. J. Davis, Alex. Ross and Henry W. Bond. Messrs. Thompson, Ross and Bond represent the Hollins syndicate, and Jas. J. Davis represents Philadelphia interests, presumably the United Gas Improvement Co.; Jas. Campbell represents his individual interests.

On January 6th the St. Louis Illuminating Co. filed a deed of trust for $500,000 in favor of the Atlantic Trust Co. to secure the issue of $500,000 in 6 per cent. 20 year bonds, which are to be distributed as stated above.

At about six o'clock Wednesday morning, January 8th, the head-quarters and main office of the W. U. Telegraph Co., corner of Third and Olive streets, was destroyed by fire. The fire originated in the basement and spread upward to the operating room on the fourth floor with great rapidity. The few operators on duty escaped hurriedly. Very little apparatus was saved. The fire department responded promptly, but the flames had made such headway before the alarm was turned on that they labored at great disadvantage, and could not suppress the fire until it had reached the roof and had destroyed the east cupola and the main switch-board. The loss is variously estimated at $8,000 to $10,000.

The telegraph officials claim that the fire originated from an electric light wire; but this is denied by the United Electric Light officials who investigated the case.

Temporary quarters were taken at 215 Pine street, and a car load of material was ordered from Chicago, which arrived during the following night. Two 40-wire cables were strung from the west cupola—which had escaped injury—across Olive street and the housetops of the intervening block to their temporary quarters. On the following morning, January 9th, the staff were ready for business, having established a Wheatstone circuit to Kansas City, to which point all business was sent for distribution.

On the night of January 6th–7th a heavy sleet storm occurred, which did great damage to all electric wires. The Bell Telephone Co., of Missouri, had 450 wires broken. The Western Union Telegraph Co. and the City Telegraph and Telephone Service suffered heavily.

On Tuesday morning, January 7th, two horses of the People's Street Car Line were killed by a fallen electric light wire on Fourth street, between Market and Chestnut. The heavy sleet storm was the cause of the falling of the wire.

At 4.30 P. M. Sunday, January 12th, a cyclone of considerable force passed through the city in a south-easterly direction, doing much damage to all electric wires. The Bell Telephone Co. had 656 wires broken. Their repairing forces were put to work immediately after the cyclone, and by the aid of calcium lights their work was continued all night, and all breaks were repaired in 24 hours.

The Laclede Gas Co. also made immediate repairs to their circuits and were ready for their night's lighting. The Missouri company being shut off from their public lighting by order of the supervisor of city lighting, attended to their commercial service only.

On February 13th the Missouri Railroad Co. will vote upon a proposition to increase their capital stock from $800,000 to $2,400,000. The object of this increase in capital is to change the motive power on their Market street and Forest Park lines, and also to take up $500,000 of their 6 per cent. 5-20 optional bonds, and repay $100,000 cash which was borrowed to complete their Olive street cable equipment about a year ago. Electric street car propulsion has made such satisfactory progress in St. Louis since they adopted the cable on their Olive street line that they are contemplating the adoption of electric power in the reconstruction of the two lines mentioned above.

At an annual election of the Missouri Electric Light and Power Co. on January 14th, the following directors were elected for the year 1890:—S. M. Dodd, J. Clifford Richardson, J. C. Van Blarcomb, Jas. W. Bell, Edward Whittaker, Thos. H. West and R. C. Kerenes.

On account of expiration of charter the St. Louis Gas Light Co. sold their entire property and rights at public sale on December 24, 1889. The Laclede Gas Light Co. was the only bidder at $4,000,000. This places the Laclede company in control of the gas business of the entire city.

The gas industry seems to have much vitality, for notwithstanding the above a new gas scheme is being brought forward; the promoters claiming that by a new process they can sell gas for heating purposes at .45 cents per thousand, and .75 cents for illuminating purposes. A bill has been introduced before the city legislature asking for a franchise. The title of the scheme is, Metropolitan Electric Light and Gas Fuel Co. of Missouri, from which it seems that they intend to enter the illuminating field at large and fight the enemy (the Laclede company) on their own ground.

The Laclede company claim that their patent—the Brazelle patent—is an infringement on patents owned by them and they are therefore, they say, not alarmed in the least by the new scheme. Be this as it may the city legislature and the public-spirited citizens are giving the new gas scheme due consideration.

St. Louis, January 18th, 1890.

PITTSBURGH.

A Superb Fire Alarm Switch-Board.—Electric Cars Started on the Pleasant Valley Road.—An Important Consolidation.—Progress of the Cable Road of the Central Traction Co.—Success of the Tesla Motor with Mining Machinery.—Extension of Business and Increase of Capital Stock by the Allegheny Light Co.—Col. Love and a Big Railway Scheme.

The City Hall is about to be graced with the costliest switch-board, in connection with the operation of the city fire-alarm system, in the whole country. The apparatus is to cost no less than $9,135. Its frame-work is of light colored mahogany. The sides and the panel are covered with artistic carvings and the entire aspect of the apparatus is extremely handsome. There is not a piece of iron employed in it; everything being steel, brass, copper and german silver. All the latest improvements in fire alarm apparatus have been embodied in this outfit, and experts who have examined the details pronounce the entire arrangement as nearly perfect as possible. Mr. Morris Mead is the superintendent of the bureau of electricity in this city, and he is very proud of this new accession to his department.

The contract for the apparatus has been accorded to the Gamewell Fire-Alarm Co. of New York.

On Saturday, January the 17th, the Pleasant Valley Electric Railway commenced operations, and as the cars sped along through the streets of Pittsburgh and Allegheny they created quite an excitement among pedestrians. The Pleasant Valley Co. is operated with the Sprague electric motor and overhead wire system.

The question of overhead wires appears to be in a dormant state in this city since Chief Bigelow of the department of public works has stated that all the wires have to be underground within the coming year.

An important electrical consolidation has been effected here. At a meeting of the stockholders of the Keystone Construction Co., the Marr Construction Co. and the Washington Carbon Co. the interests of these various concerns were merged into the North American Construction Co. The new organization went into effect Tuesday, January 21. The offices of the company will be in the Westinghouse building in this city.

The officers of the new company are J. S. Humbird, president; F. S. Marr, vice-president and general manager; H. M. Doubleday, assistant general manager, and E. H. Wells, general agent. The company employs about 400 men to do the exploiting and constructing of central station plants and street railway construction of the Westinghouse Electric Co., and also build, lease and operate central stations. The capital stock is $500,000.

The cables and the cars of the newly-built Central Traction Co.'s street car line from Wood street, Pittsburgh to Minersville have arrived here. The machinery in the power house is expected to be put up within a week and the road, will be running by February 1.

Special officer Dierst, of the Southside police department received an electric shock from a grounded wire a few days ago, and for a few moments he gave a free exhibition of jig dancing in a public thoroughfare. He was not hurt, however.

The Hercules Mining Machine Co., of this city, has for the past two years experimented with a new machine for use in coal mines. Mr. John H. Scully, of the Diamond National Bank of this city, is the president of the company. A number of tests were made to obtain a suitable motive power for the operation of the machine. Compressed air and other energies failed to operate successfully until the company tried the Tesla motor of the Westinghouse Electric Co., and now the machine is proving a great success. A considerable number of the machines with Tesla motors are being introduced in the mines of the Monongahela Gas Coal Co., and it is thought that all the mines along the Monongahela will eventually adopt them, because the machine has the great advantage of getting out coal at the lowest cost.

The stockholders of the Allegheny County Light Co. held a special meeting on January 4th to discuss the advisability of increasing the capital stock of the company. It was decided to increase the capital from $500,000 to $1,250,000. This company operates now a very large plant in this city, with the Westinghouse alternating current system. The arc light plant consists of machinery for 800 arc lights, and the incandescent plant has a capacity of nearly 30,000 incandescent lamps. The plant is situated on Virgin alley in the heart of the city, and on account of the rapidity of its extension the place is getting too small. For that reason it is thought necessary to remove the plant to a more suitable locality, where buildings are to be erected which will admit of sufficient machinery for a capacity of 100,000 incandescent lamps. The new building is to be erected at the cost of $500,000.

Mr. Love, of Philadelphia, who appeared in this city sometime ago, and told in several interviews with the reporters of the daily papers of a system of electric street car motors, is now said to be interested in the organization of a gigantic electric railroad scheme in this city. The scheme is said to be backed by Boston capitalists with a capital of $21,000,000. The idea is to build an elevated road above the highest buildings, to run from the Exposition Building in this city to East Liberty, a distance of five miles. There are to be several stations along the line, which are to be reached by rapid elevators. The transit on this road is to be accomplished within one-fourth of the time of the cable road, which means that the whole distance will be covered within seven minutes. A charter is sought by the gentlemen interested, whose names are not given at present; they are getting into shape to carry their plans into effect.

PITTSBURGH, January 20, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

THE LAW OF INVERSE SQUARE.

[116.]—In the January number of the ELECTRICAL ENGINEER, letter No. 112, page 27, I observe a comment by Mr. Harry Fielding Reid on my article which appeared in November.

The article was not written for the instruction of persons already familiar with the meaning of the equation of Laplace, nor under the impression that I had made any new discovery.

If I have inverted Laplace's reasoning I still do not see that I am "begging the question," unless I have first used the same without inversion, which, so far as I can see, I have not done.

When investigators were endeavoring to establish the conservation of energy they advanced in its support arguments based on the impossibility of the perpetual motion, which in turn is an induction from numberless experiments. Now, although all, of at least a vast majority of the scientific world, believe in the conservation of energy, the reasoning is sometimes inverted, and the impossibility of the perpetual motion becomes a deduction from the conservation of energy.

Of course, this is begging the question, if there be not sufficient evidence for the conservation of energy without the perpetual motion argument.

Assume a closed surface around a centre of force, the surface integral over the whole surface being finite and positive.

This is consistent with the assumption that the law is any function of the distance. Now, suppose this closed surface, divided into two compartments by another surface, one compartment containing the centre of force and the other being, of course, vacant. Next take the surface integral over each compartment separately.

That over the compartment containing the centre of force will in general be finite, though not necessarily equal to that over the original surface, unless the law of force be that of the inverse square.

Let us suppose it is less. Then the surface integral over the vacant compartment has a positive finite value. This, to my mind at least, is contrary to the concept of a central force. This finite positive quantity of force must either come from nowhere in particular, or else it must come from one or more definite points (centres of force) within the so-called vacant compartment.

If Mr. Reid can show that a central force is not necessarily traceable to a definite origin, or, on the other hand, that there may be definite points at which forces originate, and from which they emanate (or radiate, if he prefer the word), but which are not centres of force, then, of course, the argument of my article falls to the ground. It seems to me a part of the concept of central forces that any point capable of increasing a surface integral by incision within the surface is a centre of force. In proving the parallelogram of forces it is customary to suppose a force or pressure which is applied at one end of a line and in the direction of the line, to be transferred without gain or loss or change of direction to the other end of the line.

Is there an independent assumption in substituting for the straight line an elementary straight tube of force? If not, then the law of inverse square is true, for the case where the lines of force are straight, and by the compounding of the forces from an infinite number of elements of volume for which these lines of force are straight, we find that the force at any section of an elementary curved tube of force may be conceived to be transferred to any other section of the tube without gain or loss or change of direction, other than that which the tube undergoes at the same time.

My remarks on Maxwell's experiment, of course, stand or fall according to the truth or error of the rest of the article.

TOWNSEND WOLCOTT.
851 Greene Ave., Brooklyn, N. Y.

CRITICISM OF DEWEY'S CATALOGUING SYSTEM.

[117.]—I would like to call the attention of engineers, especially electrical engineers, to the treatment of *Engineering* in Mr. Dewey's system of cataloguing libraries. His system has much general merit, and is going into use largely in public and college libraries. It is important that errors in any part of it should be condemned by those interested, and corrected.

The whole subject of engineering runs from 620 to 629 inclusive. Thus:—

620 ENGINEERING.
  621 *Mechanical Engineering.*
  621.1 Steam Engineering.
    .2 Water Engines.
    .3 Electrical Engineering.
    .4 Air and Gas Engines
    .5 Air Compressors.
    .6 Blowing and Pumping Engines.
    .7 Mills and Manufacturing.
    .8 Mill Work and Mechanism of Transmission.
    .9 Machine Tools.
  622 *Mining Engineering.*
  [The tenths are given to subdivisions as under 621.]
  623 *Military and Naval Engineering.*
  624 *Bridges and Roofs.*
  625 *Railroad and Road Engineering.*
  626 *Canal Engineering.*
  627 *River, Harbor and General Hydraulic Engineering.*
  628 *Sanitary Engineering, Water Works.*
  629 *Other Branches of Engineering.*

Several things are remarkable in this scheme.

One is the entire absence of *Civil Engineering* as one of the co-ordinate main divisions.

Another is the putting of some of the subdivisions of civil engineering in a co-ordinate rank with 'mechanical, mining and other chief divisions of engineering.

A third is that the only recognition that there is such a thing as *Electrical Engineering* is that it is tucked in as one of the numerous subdivisions of one of the divisions [Mechanical Engineering].

This is pretty small for a line of engineering work which, from the numbers it employs, the brains it requires, the extent of specific and peculiar knowledge demanded, the provisions made for it in leading universities and technical schools, the amount of capital invested in it, its multitudinous and almost universal use, and the unlimited field it has entered upon with assurance of unparalleled growth, should certainly rank as one of the co-ordinate first divisions of the general subject, Engineering.

Will not those interested in the various departments of engineering endeavor to have Mr. Dewey revise this? Write to him. He is librarian of the State Library, Albany, New York. Express your views in any publication. Do what you can to prevent any library from following this decidedly faulty arrangement of books on its shelves and in its catalogue.

To remedy one or two great faults, let any number of the divisions 624 to 628 be put together as *Civil Engineering*, and let one of the numbers of main divisions thus freed be given to *Electrical Engineering*.

I. THORNTON OSMOND.

State College, Pennsylvania, Jan. 13, 1890.

LITERATURE.

Papers on Alternating Currents of Electricity for the Use of Students and Engineers. By T. H. BLAKESLEY, A. M. London: *Whittaker & Co.;* New York: *D. Van Nostrand Company.*

IN the first edition of these papers geometrical methods of dealing with problems relating to alternating currents were first clearly presented in accessible form for the general student. When these articles first appeared in the electrical journals it was undoubtedly a revelation to most students that harmonically varying electromotive forces could be compounded by the old well-known polygon of forces. No matter how many electromotive forces there might be, so long as they had the same period it was possible, if the problem was determinate at all, to solve it by a geometrical construction. Alternating current generators, motors and converters were studied by this method. The ease with which many of the most difficult problems can be solved is an important advantage; but it is not in this alone that the value of the method is found. It represents to the eye the exact relations of the electromotive forces and currents, and shows at a glance what results would follow the change of one component or another.

In the second edition are given the applications of the method to the study of condensers used with alternating currents, and of condenser transformers. A very interesting result is reached on page 51, where it is shown that a condenser with self-induction may, for a certain frequency of alternation, operate exactly as a closed circuit without self-induction.

The chapter on the condenser transformer shows well the conditions that must obtain for the successful use of condensers as transformers. It is not very encouraging as to their practical use in place of the dynamic induction transformers now employed.

The chapter on transmission of power is, perhaps, the most important. Here the whole subject of the behavior of two sources of alternating E. M. F. is discussed, and it is here that the advantages and great simplicity of the graphical method are most apparent. A simple geometrical diagram is made to show all the conditions of stability and instability for two connected sources of alternating currents. The author points out that it is possible for two alternating dynamos to run in series, and both do work, in case not enough power is supplied to either of them to do all the work demanded on the circuit.

In assuming the first case, of two machines coupled together, the author says: "Let us suppose a case where the sources are two in number, represented in magnitude and phase by A B, B C (fig. 19), of which B C is the smaller;" and in the subsequent discussion, the reader is led to suppose that only B C may become a motor, but it plainly appears from the figure that under certain conditions—for certain values of self-induction—it is possible for the source of greater E. M. F. to become the receiver and run in stable equilibrium as a motor. This is pointed out in the addendum to the chapter, on page 96.

The book is a very valuable contribution to the literature of alternating currents; and those who have to do with the designing of alternating current apparatus will find ready at hand the solution of many problems, and suggestions that will lead to the ready solution of almost any problem that may arise.

Practical Notes for Electrical Students. By A. E. KENNELLY and H. D. WILKINSON. The Electrician Printing and Publishing Co., London, 1890.

IN this work, the first volume of which has just appeared, will be found many matters of interest and value to the readers for whom it is intended. Those parts of the book which deal with practical details are, as the title would lead us to expect, the most important. Considerable space is, however, devoted to the statement of some of the elementary principles of the science. In the performance of this portion of their task the authors have hampered themselves by the determination, which they have announced in the preface, "to exclude all mathematical expressions and endeavor to put into words anything expressing a relation between quantities."

A good example of the disadvantage of such a method may be found in the statement of Ohm's law on pages 38 and 39.

This tendency is occasionally carried so far as to lead to the avoidance of a precise statement, even when such a statement involves no difficulty whatever. Few readers, we think, who wish to know what an ohm is, and seek for information on that subject on page 10, will be so well satisfied by being told that "an ohm is, roughly, the resistance offered by a column of mercury one meter long and one square millimeter in section," as they would have been by the equally simple statement of the exact length of the mercury column.

The work is nevertheless characterized throughout by clearness and conciseness of statement. The chapter devoted to galvanic cells is especially good; and the description of vertical current indicators will prove of value to many readers who have already acquired considerable practical knowledge of electricity. The omission of the voltameter as a means of calibration, and the failure to include mirror galvanometers in the discussion of indicators of current, would be a subject of comment in considering any completed work of this kind; but these and many other important topics, which have not found place in the volume before us, will doubtless receive their due share of attention in that portion of the series of "Notes," which is yet to appear.

By far, the most valuable portion of the present volume is that which is devoted to the study of the magnetic field. In this last and ninth chapter, which considerably exceeds in length the entire preceding portion of the book, many of the simpler algebraical formulæ are introduced, and the C. G. S. system of units makes its appearance. While the first eight chapters are written in a style which will render them chiefly useful to the beginner, chapter nine, in addition to a very excellent exposition of the well-worn facts in the domain of magnetism, embodies a summary of many important researches which have not yet found their way into our text-books. The pages devoted to Hughes's theory of magnetism, to Fleming's work on hysteresis, and to susceptibility and permeability, indeed, a large part of the chapter, will find many appreciative readers, even among those to whom most of the contents of the earlier chapters may be a very old story.

Die Elektrische Beleuchtung und ihre Anwendung in der Praxis. Verfasst von DR. ALFRED V. URBANITZKY. Wien, Pest, Leipzig: *A. Hartleben's Verlag.*

THIS little book is a fairly good exposition for the lay reader of the principles and instruments used in electric lighting. The last sentence in the book indicates, as well as anything can, the author's intention,—"We conclude the preceding work with the desire that it may assist in extending electro-technical knowledge, and may win many friends for the electric light." To the uninitiated it gives concisely, and for the most part clearly, some definite information regarding a subject generally vaguely apprehended. Perhaps none of the forces employed in modern civilization are met with such bewildered confidence in their possibilities as this same electricity. The reading of just such books as this of Urbanitzky, will do much to instruct the wondering public as to the real action of the electric current and the limitation of electric lighting. The book suffers in places from the failure of the expert to appreciate the exact difficulties which beset the way of the general reader; but the author, for the most part, understands his readers, and makes the path smooth.

The short historical sketch with which the book begins, gives a good idea of the development in the construction of both arc and incandescent lamps. The place in the book given to this sketch is poorly chosen. The lay reader does not understand the nature of the difficulties there described as overcome. If the chapter followed the detailed descriptions of the modern lamps, it would be more satisfactory.

To explain in one chapter the construction of the dynamo, and illustrate by several examples its principal types, seems a hazardous undertaking, but it is justified by the success which the author has attained. The whole section on "electrical machines" is characterized by a wise selection of the essentials to be explained and an equally wise omission of details unimportant to a fair understanding of the subject. The reader is brought directly to the fundamental principle of the dynamo, and by careful reading will get a good idea of the way an electric current is generated; and that, too, without having to form the conception of "field of force." Naturally, the subjects of "secondary batteries" and "converters" receive brief mention before the detailed description of the lamps and their accessories.

The account of the construction of the incandescent lamp lacks a little in interest, but is fairly complete. The arc light, however, is royally treated, and is made to appear in a large variety of forms. The descriptions appear to be accurate and painstaking. Chapter five treats of the accessories to electric lighting. Motive power, the relative merits of the continuous and alternating current systems, regulation of the current, cut-outs, ammeters, voltmeters, measuring and registering apparatus, etc., are here given some attention. The author closes with a brief account of some of the numerous ways in which the electric light can be used. It can be used, he suggests, by the manufacturer and the stage manager, the hotel keeper and the scientist, the railroad corporation and the oculist, and naively concludes: "And so we could enumerate and describe a much longer list of the uses of the electric light, and yet never reach the end."

We cheerfully recommend the book to those whose ideas are hazy regarding the source of the electric light, or the construction and operation of the lamp, believing that a careful reading will do much towards giving them a clear mental vision on this matter.

Notes.

MR. F. B. BADT, in his letter printed in the ELECTRICAL ENGINEER of January touching our review of his "Incandescent Wiring Hand-Book" in December, says: "In the first place my formula is not more complicated than his (the reviewer's), if you eliminate the constant and simply write the formula, $d^2 = N \times D \times K$." Unfortunately it is useless to write the formula in this way, because the factor K is itself merely a symbol for the complicated expression objected to; and as its value must be independently calculated in each case, it might as well be fully expressed at once. Again, even admitting its simplicity, Mr. Badt would still object to the simpler formula on the ground that commercially the allowable loss of potential is usually expressed in percentages of the normal potential and not in volts. But the review nowhere stated that the loss of potential should be specified in volts, except in the formula in order to make the expression more simple; and, moreover, as a matter of fact, even Mr. Badt's formula really reduces percentages to volts lost at last.

As it will be generally conceded that even "practical electricians" or wire men, as distinguished from "office electricians" by Mr. Badt, whatever the difference may be, are likely to know that 10 per cent. of 100 volts is 10 volts, or that 10 per cent of 60 volts is 6 volts, etc., it is evident that this objection must likewise be dismissed.

There was, of course, no intention to disparage Mr. Badt's desire to elevate the standard of the ordinary wire-man; on the contrary it was commended, and the fact that his formula could be stated in a simpler form was suggested as an aid to his object. He has looked at the criticism from the wrong point of view, and he should have decided the question on the merits of the case, and not uphold the complicated formula because it may now be found in extensive use.

NEWS AND NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

MEETING OF JANUARY 21, 1890.

The January meeting of the American Institute of Electrical Engineers was held on the evening of the 21st, in the new library and session room at the house of the American Society of Civil Engineers, Mr. George M. Phelps in the chair.

In opening the meeting the chairman made a brief report for the committee appointed at the last meeting to secure and present to the Society of Civil Engineers some contribution to the furniture of their new session room. The committee, he said, had met with cordial support from members of the Institute; and in selecting a modest New Year's gift to the Civil Engineers they had been guided by considerations of utility. The andirons and fire tools on the hearth were the result. They seemed appropriate and useful, inasmuch as the discussions of technical bodies, such as the Civil and the Electrical Engineers, were invariably characterized by coolness, not to say frigidity—it was reserved for Doctors of Divinity and Doctors of Medicine to develop heat in discussion—and a help toward keeping warm was therefore selected.

Professor Anthony then read a paper on "A Review of Modern Electrical Theories." (See page 43.)

The Chairman—Professor Anthony has very pleasantly led us into a realm of etherial speculation—not altogether speculation, because founded on many things known before—and I am quite sure that some of you will be glad to follow him immediately in his excursion through that vast entanglement of wheels.

DISCUSSION.

Dr. Otto A. Moses—Professor Anthony has indeed set our thoughts moving.

I presume that all of us here have been very deeply interested in those speculations, because though they may be speculations, they are the scaffolding upon which the whole science of electricity has been based. It was the pursuit of a hypothesis that led Kepler year after year through very patient investigations to the results which revolutionized astronomy. The same course led Faraday, step by step, to those determinations which culminated in what we are now first recognizing—the identity of electricity and light. So that I can say that we have all been gradually accustoming ourselves to these speculations, even though many of us are engaged in the practical uses of electricity. There are some of Professor Anthony's observations to which I would call particular attention, more especially the last, as bearing upon our practical applications. He spoke of the possibility of using the molecular action of gases as a means of transforming wave-lengths. That, I think, has been done ever since the Rhumkorff coil has been used and the Geissler tube has become so perfect an analyzer of the electric current. In that respect we have already anticipated some of these results. Let us consider what we already have. In the Geissler tube we have the attenuated gases; two disconnected poles; a current passing; and the wave-lengths broken up and the light produced. Whether we can utilize the Geissler tube to effect these immense economies that Professor Anthony so pleasantly prophesied is a question. It has been experimented upon. I have found in my short experience in life that these things come when they are needed. There are groups of ideas that must be exhausted before people will adopt others and investigate them. We have seen it in the development of all branches of electric appliances. In the telegraph, for instance, we have seen Morse using Wheatstone's method of transmission and abandoning it. We saw him commence with underground conductors and abandon them, simply because the art of that day was not perfect enough to allow him to apply them with profit. We can unearth many a theory now which has long existed, but awaited the development of the arts to be put into practice.

I would like to add a brief supplement to Professor Anthony's predictions; in no critical spirit, although I shall be running somewhat counter to the mechanical hypothesis upon which he developed his remarks. One, with great humility, must undertake to oppose himself to a theory emanating from such a mind as that of Clerk-Maxwell; but one of the difficulties in the minds of all great mathematicians is that they must put their thoughts into mechanical methods in order to be able to weigh and measure directly. If we could only divest ourselves of the habit of considering all nature to be composed of molecules, we would come into another range of thought. I see no necessity for imagining all nature split up into infinite particles—infinite in number and infinitely small and large in size. I can readily conceive of a continuity of matter. In fact that thought is no novelty. It has been woven through all science, but we are so accustomed to limitations in our contact with nature that we are apt to conceive that those limitations actually exist beyond our mere perception of them. The wonderful analogy between the velocity of electricity and light is something that is no mere coincidence. It is true that light and electricity make themselves known to us through different senses. We can conceive that there is an identity of cause, and I will throw out a hint here that may prove one step towards the solution. The earth circulates with its sister planets around the sun; it is admitted that the sun and its system of planets are circulating around some other central point. We are perfectly unaware of the speed with which we are going through space together with the sun. Now I can readily conceive that the speed with which we pass through the sea of ether may be the speed with which light and electricity affect our senses. In other words I can readily conceive, and it does not require much stretch of the imagination, that we are passing through ether at a speed approaching two hundred thousand miles a second. If you consider that hypothesis it will immensely simplify the relations of electricity and light. We find that electricity is converted into light by two or three degrees increase of the transitory heat. A little below a thousand degrees light is invisible to our eye; a few degrees above a thousand it becomes visible; in both cases caused by electricity. So that electricity and light may be considered as having an identical cause. Now that hypothesis, of the most attenuated character, is one that I think should be dwelt upon, because it may lead finally to a solution of the question as to what is the cause of electricity and of light; that is to say, their identity may be found to lie in their common relation to the motion of the solar system through the universe.

We can put no limit to the solar system's speed of circulation; but there are, no doubt, other systems within systems, and all the forces that operate upon us in nature, may be the resultant of the varying speeds around different centres. Sir William Thomson's theory that the whole of matter can be summed up in a vibration is more and more well received. The fact that matter itself is simply infinitely small vibration and circulation of atoms, leads us to believe that there are enormous forces at work, forces that change ether, or whatever it may be, into form. Why matter should be chained to place and form requires a conception of some enormous force acting upon it, and I consider that force to be based on some enormous velocity of circulation of the solar system. This may be somewhat wandering from the theme, but still it is a speculation drawn from a speculation, as an induction spark from another spark.

A Member—I have a question to ask touching the wheel hypothesis. When you wish to increase the current without increasing the heat waste it is necessary to increase the area of the conductor. I should think that would increase the number of wheels inclosed in a conductor, and therefore increase the friction by increasing the amount of slip, and therefore increase the heat developed instead of decreasing it. I am not very familiar with the theory, possibly I am making a great error, but it occurred to me that such would be the case.

Professor Anthony—As I understood it, the more wheels there are in a conductor, the less is the amount of enegy spent in causing the slip over them, because you have more surface for slips in it. What we call a given current is accompanied by certain magnetic effects. That would mean that the wheels in space, enclosed by the conductor, are revolving at a certain rate. Now supposing those all to be revolving at that same rate and you increase the size of the conductors, increasing the number of wheels there are in it; then the wheels that are in the conductors will be set revolving at a less rate instead of a greater one, because there will be greater surfaces where the slip can occur. Whatever slip there is will occur over a larger surface, and consequently produce less motion.

Professor M. M. Garver—It is rather curious to me that in the matter of the heat developed in conductors, generally speaking, all the heat developed in the conductor, as Mr. Heaviside looks at it, is an action *around* the conductor. In that connection I cannot see, if it takes place around the conductor, why the law of temperature should hold as it does in the case of metals. Take for instance the case of copper; I believe the variation is about two-tenths of one per cent. for one degree Fahrenheit. If the same law holds, for minus 500 degrees Fahrenheit there should be no resistance and no heat developed in the conductors. I believe some experiments have been made in regard to the conductivity of copper at very low temperatures. I would be glad to hear from any one who has had experience in that line of investigation.

Mr. A. E. Kennelly—It is quite unnecessary for me to add my own personal views as to what I am sure is the universal sentiment concerning the paper to which we have had the pleasure of listening. But while it is full of food for reflection, from both a theoretical and practical point of view, there is one point more that I hope may be permitted to be brought forward—that is, the great difference between what may be called a working theory and an ultimate theory. Tracing back the history of the sciences as they are called, we see how very wide-spread they were, how numerous the sciences were; how in the Greek days every activity, from the motion of a cloud, or the motion of a body in the air, or of a body leaving the hand, was supposed to proceed from some superior cause; and gradually, as knowledge increased and investigation pursued its quiet path, those forces were singled out and found to be fewer and fewer; and so to-day we stand with a certain number which we still hope will be reduced and finally embodied in one. Dr. Moses has given us a very beautiful, I might almost say a poetic view of what he calls the infinitude of nature; but I think it would be a finer expression perhaps, if he will allow me the correction, if that infinitude be considered as proceeding rather from the unity of nature. In fact if we consider the days of Polytheism, the old Mahometan cry "There is one God" stands very aptly by comparison. In the theory of heat for example there were what we call now the crudest notions prevalent about four hundred years ago as to what its nature might be. Slowly our views have become clearer; and now perhaps heat is, in its theory, more complete than any other science. But the trouble with heat has been the same as it is now with electricity—the difficulty of getting first a theory that was workable and then a theory which would account for the facts clearly and consistently. We have listened to the explanation of a beautiful theory, a theory certainly worthy of the master minds that originated it; but somehow, it does not appear as though that theory were going to be the ultimate one which would satisfy us when we come to consider nature as a whole; and although it is a good working hypothesis—a peg upon which we can hang our thoughts—it would seem that after all we may hope for some better, some clearer, some simpler conception of the universal distribution of matter throughout space than pulleys and spinning wheels. When a vacuum was supposed to be the absence of everything from space, and nature, as we read in the old books, abhorred a vacuum, gradually people began to find out there must be something left; because phenomena occurred in places that had apparently been divested of their contents, which could not be accounted for if there were nothing there; and I do not suppose that any of us have any other conceptions of a vacuum further than this one thing;—that actions go on there through a space devoid of ordinary matter, but which we cannot conceive of as acting through nothing, and gradually as light came to be considered no longer on a corpuscular theory, it became necessary to invent a new ether, and finally the question came again, if we unite the two ethers will not the same ether do for both? Then came the electromagnetic theory of light, and that required an ether. Now from the brilliant experiments of Hertz and Maxwell we see clearly that those two ethers are one and the same; at least we cannot distinguish between their properties. The ether that we suppose will propagate light, is surely not one that we can readily unite with the idea of spinning wheels in space. The mere fact that the thing is difficult to conceive of is no bar, of course, to its truth. But surely we are entitled to the expectation that nature in her infinity is infinitely simple. Surely it is in this ether that we have to investigate something which unites more readily the phenomena of gravitation of light and of electricity. If we have for example a large vessel full of incompressible fluid—water will answer—and we introduce into the water two little jets, small in respect to the whole vessel, and we cause the vessel to be hermetically sealed, full of water, with those two jets in it; then if we force water out of one jet, back through the other, causing a circulation to take place through that liquid, we shall find—with the one reservation that there shall be no vortex motion in the liquid—that all the particles will advance in ranks—shoulder to shoulder and eyes front—and the lines that will be pursued by the individual particles are, strangely enough, the lines which are followed, we have every reason to believe, by magnetism, by heat, in its permanent state, through solid bodies, and by gravitation. Surely there is some grand principle underlying that great class of phenomena which some day in the future will join them all into one coherent mass, and by which we shall see not only electricity but all the other forces of nature united.

The point that Professor Garver mentioned about the conductivity of copper at a very low temperature is one which has certainly a very great practical interest, although we are not likely to be able to live in a climate where for the sake of our conductors we can submit to two or three hundred degrees below zero. But I think—and I have no doubt others here will correct me if I am wrong—that experiments have been made at minus 40 degrees centigrade, and they showed a very large increase in the conductivity of copper, and the coefficient of temperature was very much larger at that point than it was higher up the scale; and in fact the late Sir William Siemens had a very interesting theory, in which he assumed that the resistance at a very low temperature was a limited amount which was very small indeed and rose rapidly at first and slower and slower afterward. That is contrary to our orthodox views about conductivity of copper for high temperatures, but it is a view which is interesting in itself.

Mr. Townsend Wolcott—Regarding the existence of a medium, Professor Anthony has given voice to the most general opinion in saying that action at a distance is unthinkable. I believe this is the view which Sir Isaac Newton took; but it must not be forgotten on the other hand that Roger Coates said that there is no more *a priori* reason for disbelieving in action at a distance than for any other experimental facts that we have; and it is this same Roger Coates of whom Sir Isaac Newton said, in speaking of his untimely death:—"Had he lived we should have known something." I think that a part of the difference between two classes of thinkers arises from their having a different conception of the meaning of the word medium. In the present state of science, if we do not make the word medium mean too much, it is, in my opinion, practically demonstrated that there is a medium. If we say that action at a distance through space—vacant space—is unthinkable, what do we mean by space? If we mean simply extension, the concept of extension being simply three dimensions, it is unthinkable. But in conceiving of a medium we are too apt to make the word mean too much. Now Professor Stokes has shown that the luminiferous ether acts like an elastic solid; that is to say, the mathematics of solid elasticity apply to the ether; but if the ether be an elastic solid it must be an exceedingly solid kind of a solid. I forget how much pressure there would have to be, but it was something enormous. Now we know that the ether is not such a solid as that. Again taking the modern theory of the action of the dielectric—Faraday's theory, we will call it—it is a stress in the dielectric. Now, the mathematics of stress are equations similar to the equations of the stress in a solid body—that will apply to similar electric phenomena in a dielectric. However, there can be no real stress in the sense in which we understood the word, because the very bodies which are not susceptible of sustaining a stress are the ones which are the best dielectrics. In fact a vacuum, which we do not consider a body at all, is a dielectric, and according to some electricians it is the very best of insulators, and metals which generally are capable of sustaining a great deal of stress are all conductors, and according to the electrical theory are the bodies in which the state of electric stress cannot exist; it gives way immediately and produces what we know as current.

Dr. Michael Pupin—I wish to express my feeling of obligation to Professor Anthony for his lecture on the modern theories; and with his kind permission to add a few comments as a supplement to his review. We know what ideas Faraday had about dielectrics, and the function which a dielectric has to perform in the transmission of the electric force from one part of space to another. We know that Faraday supposed the dielectric to be filled with small particles—we will not say molecules or atoms, because we do not know whether these things really exist—we say simply small particles which have the property of polarity. In what that polarity may consist we do not know. We may suppose it is of the same kind as the magnetic polarity in the case of soft iron—that every small particle is in fact a perfect magnet, having a positive and a negative pole. That theory has been worked out by Professor Helmholtz, and he reduced the equations for the distribution of the stress in the dielectric, exactly the same as Maxwell did. In fact the equations which Helmholtz obtained are somewhat fuller. Now assuming it to be true that a dielectric consists of very small particles each one having the property of polarization, from that one property of the dielectric all the electro-static and all the electro-magnetic phenomena can be explained. I do not see that it is necessary to go any further into the consideration of any wheels working with any other wheels. To be sure Maxwell did work out a theory, I think in 1862, to which reference has been made this evening; but he gave it up, and in his second volume he refers to this theory in a sort of off-hand way, saying that some years ago he worked out a theory of electricity on the vortex motion hypothesis of Sir William Thomson; that could be found there, and taken for all it was worth. Now Professor Helmholtz, supposing the medium to have only these properties, namely, the properties of polarization, and—referring to the stress in the metal—says that if there is any electric disturbance, whether it be an electro-static disturbance or an electro-magnetic disturbance, the same disturbances we have in the conductor must be propagated in the whole dielectric, because disturbance in the electric state of the conductor will cause a disturbance of the metal, and that disturbance of the metal gives the electro-magnetic action.

Helmholtz's papers are not published yet (but I expect they will be published very soon); to be sure they do not contain anything new, because these things have been worked out before by Sir William Thomson, and I think by Maxwell at first.

Another point. Every one of the speakers this evening has spoken about forces. The term force is a very elastic term and may mean anything. In fact, I think every man has his own idea about force. But if we are to discuss and use the term force we must have a common definition of force. What is force? Where are we going to find the definition of it? I think if we are to treat sciences from the mechanical standpoint, then we must define force mechanically. That is, we must take motion as containing the full definition of force, and if you do that you will fall back necessarily on the Newtonian definition of force, that is, as producing nothing but motion; that is the elementary definition of force. When we speak of electric forces and magnetic forces we certainly deal with something which will produce more than motion alone. In fact I think that it is not unreasonable to believe that Faraday was led to his investigation of the functions of electrical phenomena by considering Ampere's integral law, knowing that a current flowing through a conductor will act upon a magnetic pole just the same as if the wire was an empty shell having a magnetic moment equal to the strength of the current. Now, in every department of natural science it is always desirable, and in fact it is the highest aim of every physicist to deduce, not the integral law but the differential law. Newton achieved his great success when he found the differential law—the law of universal gravitation. Ampere thought his integral law would be of little use to him if he did not know the differential law; namely, the law which determines the action of each element of one conductor upon each element of any other conductor or upon itself. He said, let us now resolve this integral action into elementary actions. He did it, and he found that each element of the conductor—supposing it to act upon a pole or upon an element of another conductor with a force which is proportional, but which does not act in the line of action between the two particles—exerts a force which does not act in the line connecting two particles, but acts perpendicularly to the line. Another differential law has been lately deduced—in the last twenty years—by Maxwell, Weber and Helmholtz. Some of these laws suppose that there is not only a force perpendicular to the line of these two particles, but also that there is something that tends to turn the element; so that we have to deal here not only with forces which are determined by laws of mechanics, but with forces that lie entirely outside of that. Therefore we have always carefully to distinguish what we mean by force. Is it purely mechanical force, is it a force which produces, besides motion, something else? We cannot speak of chemical forces in the same way as we speak of mechanical forces, because mechanical forces are forces limited by the definition of Newton, and they produce nothing but the motion in the mass. Chemical force produces heat, it produces chemical composition and decomposition; it produces light and it may produce motion also. I think Faraday when he saw this elementary law thought that he had not to deal here with pure forces, such as the gravitating force, where the force is always in the line connecting the two points acting upon one another: and that it is not an elementary force, and if it is not an elementary force it may perhaps be explained by some mechanism.

The other point which I would like to bring up refers to the conductivity of metal. It has been said here that the rule—I won't call it a law, I will say the rule—is that every metal increases its resistance with temperature, and that according to calculation at certain low temperatures the metal ought not to offer any resistance whatever. The fallacy is self-evident; and that fallacy would be self-evident not only in the case of the rule, but also in the case of the law. When we speak of a law we do not mean something absolutely true. Clifford has defined the meaning of law;—a law is true only in those conditions under which the construction of the law was observed. The law of heat, the law of light, the law of electric current, all were observed, not in a vacuum, but in space; not in a temperature of several million degrees, but in temperatures which we can get ranging from minus 80 degrees to, perhaps, 1000 degrees centigrade. The law above those limits may be true or may not be true. Every law may be represented by a certain curve. Where the curve does not run from minus infinity to plus infinity we know a very small part of that curve; the rest we do not know.

Professor Garver—I see that I was misunderstood. I was speaking in regard to the change due to temperature as being incompatible with that due to the action taking place in the medium inside of the conductor; and at first sight it seems that the variation in conductivity due to the temperature in the conductor was at variance with the view that the action took place outside instead of inside the conductor. Since thinking it over, I have arrived at what seems to be a plausible answer to my own question, namely:—that the conductor being actuated by heat, the particles are in motion due to the action of heat while in that condition. Now, as the temperature of the conductor goes down, the heat action becomes less and less, and it then approximates to what I believe it is supposed to be—a hole through the medium.

Mr. Nikola Tesla—I want to suggest a practical solution on which I have not taken a patent, but which is cheerfully offered in case any gentleman wants to patent it; and that is, there seems to be no doubt to-day that light and electricity are one and the same, and that between them there is only a difference in degree. Now the question resolves itself into how to produce a number of undulations that would equal those of light, which you can perceive. We know that if you put two coils in inductive relation you can, by passing through one coil an undulating current, produce in the other two distinct currents. From that secondary we can again act in the same manner upon a third. I have figured that at that rate it would require about twenty-three conversions. If you assume an efficiency of 80 per cent. in the first you can assume one of two per cent. in the last secondary, which is the twenty-third.

While we are convinced that light and electricity and electro-magnetic action are the same, yet there seems to be a difference between light and electricity in this way—that we cannot maintain light in a static condition. On the other hand we can maintain electricity so. Again light and magnetism are similar in this respect. We know well that we can magnetize a steel bar and it will hold magnetism indefinitely. We can magnetize also a soft iron bar and it will lose the magnetism soon. Now there seems to be, from what Professor Anthony has so admirably set forth, a possibility of producing a magnet of such qualities that it would for an indefinite time, say for a year, or two years, or three years, discharge continuously its magnetism after the cessation of the current which energized it. I attempted in my early days to do that, but it does not work.

We can store light for a moment. That is if we expose certain bodies which take on light and keep it for awhile—if we expose such a body to an arc light or to a source of very intense light we will find that it will take up and emit light for a short time; but when the source of light is intercepted the reproduced light will instantly fall down and the little that remains will gradually disappear, similar to that little remnant of magnetism that remains in the big bar of iron. If we plot the curves for magnetism and for light we find them to correspond. We know that electricity can be stored (I understand now the difference which Professor Anthony has brought out between potential difference and electromotive force), I mean we can take a condenser or a Leyden jar and store up electricity in any quantity, so to speak, and keep it there for a considerable time, and then discharge it at will. We cannot do so with light nor with magnetism; and yet we know that all these are really one and the same thing, and that there is only a difference of degree.

Dr. Pupin—I would like to ask Professor Anthony to define the term "electromotive force."

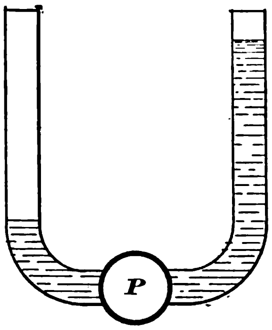
Professor Anthony—It is one of the most difficult things in the world of which to give a definition, and I never pretended to any ability at giving definitions. We all know that in a battery there is something that develops an activity. We know that the conductor gets warm. We know that around the conductor there are what we call magnetic forces, and I believe that there is an activity set up in the whole space around it. Now, whatever that is inside of the battery that gets up this agitation I call electromotive force. Furthermore, we know that if we move a wire across the magnetic lines of force there arises something which, if that wire form a closed circuit, will produce what we call a flow of electricity. We know it is a flow of electricity because under proper conditions the wire will get warm, because also there are magnetic effects developed by it. There is something that takes place—an agitation is set up in that wire—and I consider that something, I do not pretend to define it, I do not pretend to know what it is, but there is something there in consequence of the movement of that wire across the magnetic lines of force that constitutes what we call electromotive force. It is something, to use the language of electrical theory, that puts electricity in motion, and there is just the action I referred to in the paper, in which we may have electricity in motion, taking this theory of a current in a conductor, without any difference of potential. Suppose, for instance, I have a perfect circle of wire, and I thrust the north pole of a magnet perpendicularly into the centre of that circle. We know that lines of force cut that circle, all around, in every part of it; and my idea is that when that magnet is thrust through there we know that a current is set up around that wire; that when that magnet is thrust through, whatever there is that constitutes a magnetic field acts in some way to set up this current, and acts in every part of the wire so that there is a current set up without there being any difference of potential between any two points.

Dr. Pupin—How would you measure the heat produced in the wire? Is that subject to Joule's law?

Professor Anthony—I should say so, certainly. Electromotive force is measured in the same *terms* as difference of potential, of course.

Dr. Pupin—It must be the same.

Professor Anthony—I do not think so any more than in difference of level. We measure difference of pressure, for instance, by difference of level in case of water. To illustrate it (illustrating on the blackboard), here we have a tube. Here, at P, we have a pump in that tube. I set the pump turning. The water before was at the same level in both upright branches. I now set the pump turning and the water comes down one branch and goes up the other. That difference of level will measure the difference of pressure; but that pressure was produced by turning the handle of this pump. Now the turning of the handle I call the water moving force. This constitutes a difference of potential, a difference of gravity potential which opposes my turning of the handle.



Dr. Pupin—Therefore the work done measures the difference of level?

Professor Anthony—It may be measured by the difference of level.

Dr. Pupin—But the work done measures the difference, and the turning of the handle measures the work. In the same way the electromotive force is not a force at all in the usual sense of the word. It is the work done to make the difference of potential, and that is what the difference of potential is—the work done.

Professor Anthony—Suppose that we do not produce any difference of potential, as in the case of the closed ring conductor into which the pole of a magnet is thrust?

Dr. Pupin—But I think we do. That is a well-known problem. The difference of potential is equal to the work done. Substitute for each element in such a closed ring an infinitely small Daniell element, all around. Of course that is practically impossible, but it is conceivable. We can place infinitely small Daniell elements, connecting them together around the circle so that they will form a closed circuit. Is there not difference of potential there?

Professor Anthony—If you have them infinitely small so that each Daniell element acts on each element of the wire, then I should say there was no difference of potential from one end to the other, and we have the electromotive force of the Daniell element producing the result entirely and nothing else.

Dr. Pupin—But in that infinitely small battery between each pole there is a difference of potential between each two poles—in every one of those infinitely small batteries—there is a difference of potential. So I may say between each one of the infinitely small elements of the wire there is a difference of potential, and they are connected in series and the current runs around.

Professor Anthony—Let us take it in another way. Suppose there is a circular tube containing a gas or liquid, whichever you please. Now, can we not conceive of such a thing as something acting simultaneously upon every single element, no matter how many you consider there may be of them, and acting all at once so that every one of these elements will move forward at the same instant, and that there is no difference of pressure anywhere in that case. Now difference of pressure is what I consider as equivalent to difference of potential. In other words, what we call difference of potential electrically is due to a disturbed electrical distribution, and until you have a disturbed electrical distribution there is no difference of potential. Now, in the wire where we have a perfect circle and thrust into it the magnetic pole, if we act on every element of that wire simultaneously there is no disturbed condition of potential, and after you have stopped the magnetic pole you can conceive that your electricity has been shifted around through the whole of it without there being a disturbance there—without any difference of potential when you are through. You stop the movement of the magnet; the current stops. Your electricity does not fly back again. But let us cut that wire in two and leave an opening in it. Now force the magnetic pole through the middle and you tend to make a motion around in the same way. Electricity is heaped up at one end making pressure there. It goes away from the other end; and the moment your magnet stops the motion then the electricity flies back and produces a current the other way.

Mr. Francis B. Crocker—It seems to me that the last illustration of Professor Anthony's will give us a solution of the problem and reconcile both sides of this controversy. He assumes that the wire is opened at a certain point, and if you thrust a magnet in you will get the total difference of potential which is a calculable quantity; we could calculate that—predict it from known electric and magnetic effects. Now it seems to me that when the gap in the ring is closed you get that difference of potential spread over the entire circle, and that difference of potential spread over the entire conductor produces the current. Now it is heaped up at the opening because it cannot pass that point, there being no conductor there. But it seems to me the same total potential difference—which is what always produces a current, or rather which usually produces a current, to make the statement a little less objectionable—is heaped up there; but if we close that conductor at that point, isn't it natural that that potential should be distributed uniformly throughout the entire circle? But being distributed in that way it produces the same effect as it would if it were concentrated at one point through the same resistance, and it seems to me that although there is no difference of potential which you could put off by itself, yet the same difference of potential exists throughout the circle. In other words, the integral of the difference of potential is the same in both cases, because the flow in that circuit and the $C^2 R$—the Joule effect, and all those other electrical phenomena which we understand perfectly,—will be precisely that due to the difference of potential which we get when we open the circuit. I do not think there is a gentleman here who will doubt that fact, that the difference of potential which we get when we open the circuit, as assumed by Professor Anthony, is the same potential difference of electromotive force which produces the current and heating effect and magnetic effect; and, therefore, if that heating effect which we get from the closed circuit corresponds with the difference of potential which we get when we open the circuit, isn't it not only natural but almost necessary that we have the same difference of potential spread throughout the circuit and producing a current through the same resistance? And I should say that, theoretically, the way to look at it was to divide it up into elements. It would be utterly impossible to treat any complicated phenomena in force without assuming them divided up into elements, throughout which elements you can make certain assumptions. That is, you have to differentiate. You have to take a certain element and treat it by itself. Taking a certain element anywhere we have a certain difference of potential, a certain resistance and a certain resulting pressure. Assume the ring, for instance, to be divided into a thousand equal portions. Then while with $\frac{1}{1000}$ of the difference of potential found when the circuit is open we will have 1000th of the resistance of the whole ring, and therefore we will have the same current that we would with a thousand times potential difference and a thousand times the resistance. That seems to me to be a particular case. It is a limiting case; and what is true just before the limit is true at the limit, according to Newton. Therefore, if we make it uniform and make a limiting case out of it, a case which is as far as we go in that direction, then what is true just before the limit is true at the limit.

Mr. Wolcott—Mr. Crocker's idea of the circulation of current in the ring is a good deal like the relation of east and west on the globe. We can have a point west of New York, and by going in the other direction it will be east of New York. If you take Mr. Crocker's conception and integrate the difference of potential all around the ring, when you get back to the starting point, that point has two potentials, and so it must be. It is like any other cyclic region. One of the most familiar cases of that is the magnetic potential. In an infinite straight conductor the potential at any point has an infinite number of values, but it is only on some such conception as that that you consider there is any difference of potential. That is by going around until you come back to the same point you have increased the potential by the cyclic constants of the curve.

Mr. Kennelly—I think we are very much indebted to Professor Anthony for having called attention to one of the leading misconceptions of the day. There is a constant conflict between difference of potential and electromotive force, and I think nothing can be better in a society of this kind than to settle such differences. I think Professor Anthony has given us a very clear solution in this way, that whatever produces a current is electromotive force; that electromotive force may or may not be accompanied by a difference of potential. We do not recognize potential as we recognize current. We are led to it by a series of abstractions. Potential was introduced from a purely theoretical and mathematical basis. The potential function first existed in gravitation. It was introduced into electricity by similarities which exist between gravitation laws and electrical laws, in their mathematical form; and potential is something which causes work to be done—in virtue of which work can be done. The potential is measured by work which can be done by bringing a unit of electricity to the point where potential is measured.

Dr. Pupin—I do not agree with Mr. Kennelly that the potential is a mathematical conception any more than I would agree with him that the work is a mathematical conception. Who would say that to raise a barrel of flour to the gallery above us here was a mathematical conception? To charge a conductor with a certain amount of work. If we do not stick to this term work we cannot make a step of progress, because we cannot take in the conservation of energy. Potential is not a mathematical conception. Potential is as concrete as I am, standing here. It is the amount of work done. Mr. Kennelly said that the difference of potential is something which causes the work to be done, and a little while before it was said that electromotive force is the cause of the electric current. Now these two things seem to be one and the same, because to cause the current to flow is the work done; but I will not discuss that any more seeing that my colleague [Mr. Crocker] has expounded my idea of this circular conductor in a very nice and masterly way.

At the close of the discussion, the chairman announced the next meeting of the Institute for the 18th of February, when a paper will be read by Mr. William Maver, Jr., and the topic will be, "The Practical Working of New York's Electrical Subways."

Adjourned.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.—GROWTH OF MEMBERSHIP.

The following-named gentlemen have been elected to Associate Membership in the American Institute of Electrical Engineers since the publication of the revised catalogue, November 1, 1889:—

AT COUNCIL MEETING, NOVEMBER 12, 1889.

Wm. C. Benbow, electrical expert, Thomson-Houston Electric Co., Boston, Mass.

Geo. P. Wardell, U. S. Electric Lighting Co., 19 Cedar street, Newark, N. J.

I. E. Winslow, railway expert, Thomson-Houston Electric Co., New York.

Sidney Z. Mitchell, electrical expert, N. W. Electrical Supply and Construction Co., Seattle, Washington.

F. H. Smith, civil engineer, 227 E. German street, Baltimore, Md.

Franz Schulze-Berge, assistant, Edison's Laboratory, Orange, N. J.

Frankland Jannus, solicitor of patents, 928 F. street, Washington, D. C.

Hammond V. Hayes, electrician, American Bell Telephone Co., Boston, Mass.

Francis G. Daniell, railway expert, Thomson-Houston Electric Co., 403 Sibley street, St. Paul, Minn.

H. F. Parsell, Jr. (student Stevens Institute), 31 E. Twenty-first street, New York.

Henry G. Fiske, electrician, Croton Magnetic Iron Mines, Brewsters, N. Y.

Chas. W. W. Spicer, Edison Phonograph Works, Orange, N. J.

Charles Gorton, electrical engineer, Clark Bros., Belmont, N. Y.

John J. Moore, Thomson-Houston Electric Co., 425 E. Twenty-fourth street, New York.

DECEMBER 3, 1889.

Huntington Lee, representative F. H. Whipple, 18 Cortlandt street, New York city.

Captain S. W. Roessler, Corps of Engineers, U. S. A., Willett's Point, Whitestone, N. Y.

E. V. Bailliard, electrical inspector, Electrical Accumulator Co., 44 Broadway, New York.

Chas. J. Bogue, electrical expert, New American Arc Light Co., 256 W. Fortieth street, New York city.

JANUARY 7, 1890.

Alfred A. Dion, electrician, Intercolonial Railway, Moncton, N. B.

John E. Davies, Professor of Physics, University of Wisconsin, Madison, Wis.

Gilbert Wilkes, assistant to inspector of electric lighting, Navy Department, Washington, D. C.

Justus B. Entz, electrical engineer, 1,065 Madison avenue, New York.

Geo. W. Moss, station manager, C. & S. A. Tel. Co., Tehuantepec, Mexico.

H. Doijer, assistant of physics, Polytechnical School, Delft, Holland.

Wm. J. Hancock, superintendent of telephones, Department of Public Works, Perth, Western Australia.

Harris Henry Eley, W. C. & S. W. Telephone Co., Bristol, Eng.

Will F. White, secretary and treasurer Western Engineering Co., Kearney, Neb.

Donald M. Bliss, electrician, Canada Electric Co., Amherst, N. S.

Alexander S. Brown, general manager Morristown Electric Light, Heat and Power Co., Morristown, N. J.

The following Associate Members have been transferred to full membership, upon approval of the Board of Examiners:—Dr. Chas. B. Dudley, Altoona, Pa.; J. T. Marshall, Harrison, N. J.: Leigh Carroll, Birmingham, Ala.

COLLEGE NOTES.

Cornell University.—Sibley College.

The course in mechanical laboratory practice for the seniors in Electrical Engineering has been modified so as more completely to meet their requirements. Preparations have been made for some interesting mechanical and electrical tests. A completely equipped Thomson-Houston arc light plant has been placed in the laboratory. The power is furnished by an "Ideal" engine which was constructed in the Sibley machine shop. A Brush constant current motor has also been placed in this "station," the Thomson-Houston dynamo furnishing the current. Complete efficiency tests of the engine, dynamo and motor will be made under various conditions. The work will be under the general charge of Professor Smith as heretofore; Professor Ryan will have charge of the electrical tests.

A new system of distribution of incandescent lights about the campus is being considered by Professor Ryan. An Edison plant will furnish lights for the buildings which are nearest to Sibley. The more distant buildings will be supplied from a Westinghouse alternate current machine. An accumulator system will furnish light, if needed, during the day, or at anytime when the dynamos are not running.

A Pritchard electric water wheel governor has been received by the department. It is expected that with this governor the turbine furnishing power for the Sibley shops will be regulated sufficiently well to be used for the new incandescent plant.

At a recent meeting of the Electrical Association the following officers were elected for the ensuing term—J. W. Cowles, president; G. D. Hulett, vice-president; H. P. Broughton, secretary.

The following are the thesis subjects chosen by the seniors in Electrical Engineering:—H. P. Broughton, "The Vacuum of the Glow-lamp;" H. Cochrane and E. C. Sickles, "The Design of an Electric Lighting Station for the Cornell University Campus, Using Water Power;" P. A. Calisdell, "Effect of a Series Coil on the Neutral Point of a Dynamo;" J. W. Cowles and L. W. Healey, "A Test of the People's Electric Railroad Line at Scranton, Penn;" S. B. Fortenbaugh and H. A. Sawyer, "Hysteresis;" A. H. Herschel and E. A. Wilhelm, "A Study of the Converter and its Efficiency as Influenced by Heat;" G. D. Hulett and S. J. Larned, "Efficiency Test of the Thomson-Houston Electric Street Railway at Syracuse, N. Y.;" A. B. Levy, "A Study of the Arc Light and Arc Light Carbons;" M. Levy, "The Effect of Electricity on Traction;" J. E. Greenawalt and J. S. Loomis, "A Theoretical and Practical Investigation of the Brush Electric Motor;" D. B. Kennedy, W. H. Powell and J. C. Ramage, "A Study of Hysteresis as Exhibited in the Cores of Armatures and Transformers;" E. A. Rumsey, "The Design, Construction and Testing of an Electric Motor;" W. B. Tobey and G. H. Walbridge, "Test of the Stanley Alternate Current Arc Light Dynamo;" H. F. Thurber and John A. West, Jr., "Determination of the Magnetic Curves of Various Grades of Iron;" W. N. Smith, "The Application of Electric Motive Power to Elevated Railways;" M. E. Thompson, "A Study of Electric Meters;" O. A. Stranahan, "The Design of an Electric Lighting Station for the Cornell University Campus;" F. F. Goodwin, "A Study of Arc Lamps."

A large amount of original work is being done by seniors in the physical laboratory in the way of investigations of different electrical phenomena, and in the construction and calibration of instruments to be used later in the year for their thesis work.

An interesting set of experiments has been made by M. Levy, '90, to determine the effect upon friction of a current passing through the surface of contact of iron sliding and iron rolling upon an iron track. With a 20-ampere current the co-efficient of friction was increased about fifteen per cent. F. C. Caldwell, '90, is continuing the work of Archbold and Teeple, '89, in the investigation of the "Ball and Point Effect with Alternating Currents." He proposes to make a study of this phenomenon in hydrogen, carbon dioxide, and air at different temperatures and pressures. W. G. Rappleye, R. G., is making a detailed study of the quadrant electrometer invented by Professor H. J. Ryan, and described by him at a recent meeting of the American Association for the Advancement of Science.

As has been the custom in previous years the spring vacation will be spent by a large number of the students on inspection tours. This year two routes have been arranged for the students in electrical engineering. One section will visit Philadelphia and New York, the other will visit New England by way of New York, returning to Ithaca by way of Troy and Schenectady.

THE EDISON GENERAL ELECTRIC COMPANY'S ANNUAL MEETING.

The Edison General Electric Company's annual meeting was held, January 20, at 44 Wall street. The first annual report of the company was read, and trustees for the ensuing year were elected as follows:—C. H. Coster, Joseph S. Decker, Thomas A. Edison, J. H. Herrick, Samuel Insull, E. H. Johnson, A. Marcus, Carl Schurz, Francis S. Smithers, Henry Villard, and J. Hood Wright. All of the old trustees were re-elected with the exception of Mr. Marx, whose place was taken by Mr. Decker. A meeting of the Board of Trustees will be held shortly, and Henry Villard will probably be elected president, and A. Marcus, secretary.

The first annual report, after reciting the purpose for which the Edison General Electric Company was formed, viz.: the acquisition of the properties of the Edison Electric Light Company, the Edison Machine Works, the Edison Lamp Company, and Bergmann & Co., continues as follows:—"A basis of exchange was offered to all stockholders, and in pursuance thereof this company has acquired: (1) 14,003 shares out of the 15,000 of the capital stock of the Edison Electric Light Company; (2) the total capital stock ($750,000) of the Edison Machine Works; (3) the total capital stock ($750,000) of Bergmann & Co.; (4) the total capital stock ($250,000) of the Edison Lamp Company. The purchase of the manufacturing companies carried with it the acquisition of the stocks of the Edison United Manufacturing Company, and of the Canadian Edison Manufacturing Company. * * * *

The properties of the Edison Electric Light Company are personal, consisting almost entirely of patents acquired from Thomas A. Edison, and of bonds and stocks received as license fees from local illuminating companies throughout the United States. * *

The United Edison Manufacturing Company has been reorganized, and is now working with a capital of $1,000,000, $500,000 of which has been paid up. The Canadian Edison Manufacturing Company has charge of the Edison manufacturing business, except the making of lamps, in Canada. Its shop is at Sherbrooke, near Quebec, and 175 men are at present employed. The Sprague Electric Railway and Motor Company has at present in use 3,000 of its motors, of all classes, applied to no less than 150 different industries, and varying from ¼ to 75 h. p. each. The number of street railway cars equipped with electric motors during the last year by the company was 551. It was first decided to acquire only a partial interest in the capital stock of this company by the purchase of the entire issue of its preferred stock ($400,000) for cash at par, with a bonus of $120,000 in its common stock. Since that time the Board of Trustees have resolved to offer to the holders of the outstanding common stock of the Sprague company ($880,000 out of a total of $1,000,000) to exchange their holdings for an equal amount of Edison Electric Light Company's stock, 66⅔ per cent. in dividend stock, 33⅓ per cent. in trust certificates. The stockholders have accepted the proposition, and the exchange of stock will soon be made.

During 1888–1889 the receipts of the Edison Electric Light Company from lamp royalties and from interest and dividends from licensed companies were $160,520.24, showing an increase of $46,529.13 over the preceding year. * * * * * *

After all bad and doubtful debts have been charged off, and after making a liberal allowance for depreciation of plant, dividends were declared by the Edison Machine Works, by Bergmann & Co., by the Edison Lamp Company, and by the Canadian Edison Manufacturing Company for a total of $587.50. As the earnings of the Edison Electric Light Company over and above its outlays for patent litigation and ordinary expenses were largely represented by the securities acquired from the local illuminating companies, it was deemed better to let these accumulate in the treasury. The net accumulation by the Light company during the year ending October 1, 1889, amounted to over $150,000. * *

The new business in sight in every department is on such a scale that if the company succeeds in increasing its capacity sufficiently to execute it, the gross receipts in 1890 will be twice as large as in 1887–1888.

Extraordinary activity may be expected during the present year, in consequence of the erection of a number of new central stations for the distribution of light and power in New York, Boston, Chicago, Milwaukee, and other large cities. The income of the Edison Electric Light Company from license fees in 1890 promises to be so large as nearly to double its present holding of securities of local companies, and the new plants insure orders to the amount of several millions to the company's manufacturing establishments. There is every indication, too, that the electric railway business will continue to grow at a rapid rate. The sales of plants for isolated lighting also show a great increase.

The following is the company's statement:—

BALANCE SHEET OCTOBER 31, 1889.

		DR.
Property accounts:—		
Permanent plants	$70,197 56	
Rental plants	25,345 80	
Supplies	5,807 11

	$463,656 63	
Less amount provisionally transferred by item next below	105,000 00	
		$358,656 63
Special profit account		105,000 00
		$3,073,790 86

STATE ELECTRIC LIGHT ASSOCIATIONS.

The efforts of Mr. Allen R. Foote, chairman of the committee on legislation of the National Electric Light Association, in organizing local associations in the several states are meeting with much success.

The Rhode Island State Electric Lighting Association was organized January 7 at a meeting of central station companies, doing business in the state, at which a majority of the companies, and about seventy-five per cent. of the capitalization, in the state was represented. Letters were read from officers of companies who could not attend, expressing their approval of the movement and pledging their co-operation.

The organization was effected by the election of the following officers:—*President*, Saml. P. Colt, Bristol Electric Light Co.; *Secretary*, Saml. G. Stiness, Pawtucket Gas & Electric Light Co.; *Treasurer*, Marsden J. Perry, Narragansett Electric Lighting Co.

The officers of the association constitute its executive committee.

The New Hampshire Electric Light Association started its career January 9th.

The response to the call for the meeting of central station was nearly unanimous; over eighty per cent. of the capital employed in central station lighting in the state being represented in person, and much of the remainder by letter.

The desirability of forming a state association was fully discussed and the proposal was cordially endorsed.

The organization was effected by the adoption of by-laws and the election of the following officers:—*President*, Alonzo Elliott, Manchester; *Vice-president*, F. W. Eastabrook, Nashua; *Secretary* and *Treasurer*, Edgar Woodman, Concord; *Executive Committee*, Alonzo Elliott, Manchester; F. W. Eastabrook, Nashua; H. W. Burgett, Dover.

A resolution was adopted directing the secretary to send an invitation, with a blank application for membership, to every central station company in the state.

The Maine Electric Light Association:—The electric central station companies in the state of Maine held a meeting at Portland, and organized a state association, on Saturday, January 11.

The meeting fully represented the electrical central station interests of the state and was clear headed and decided in its action.

An association was organized under the above title by the adoption of by-laws and the election of the following officers:—

President, Geo. P. Westcott; *1st Vice-president*, J. W. Wakefield; *2nd Vice-president*, F. M. Laughton; *Treasurer*, W. R. Wood; *Secretary*, F. A. Sawyer; *Asst. Secretary*, Geo. E. Raymond; *Executive Committee*, Geo. P. Westcott, Portland; J. W. Wakefield, Bath; F. M. Laughton, Bangor; W. K. Dana, Saccarappa; W. E. Maxey, Gardner.

A copy of the by-laws and an application for membership blank will be sent to every central station company in the state. It is expected that no company will be without a membership.

MICHIGAN ELECTRIC LIGHT ASSOCIATION:—A meeting of the companies doing business in the state of Michigan was held at the office of the Brush Electric Light Co., Detroit, January 17, to organize a state association.

The association organized by adopting by-laws and electing the following officers:—*President*, Geo. Peck, pres. Edison Illuminating Co. of Detroit; *Vice-president*, Jas. R. Dee, general manager of Peninsular Electric Light and Power Co., of Houghton & Hancock; *Secretary* and *Treasurer*, Jos. E. Lockwood, general manager of Brush Electric Light Co., Detroit; *Executive Committee*, George Peck, Detroit; Jas. R. Dee, Houghton; Jos. E. Lockwood, Detroit; W. H. Powers, Grand Rapids.

One vacancy in the committee was left to be filled after the filing of membership applications.

The secretary was directed to send a copy of the by-laws and a blank application for membership to every company in the state.

The association will give its first attention to the establishing of a general system of rules and regulations for the wiring of buildings, so as to secure the safest and best construction and service.

The ILLINOIS ELECTRIC LIGHT ASSOCIATION was formed, January 18, at a meeting held in the rooms of the Chicago Electric Club. Details of the organization will be found in Chicago correspondence (page 64).

A resolution was passed directing the secretary to have the constitution printed, also blank form of application for membership, and a form to secure sundry items of data, and to send copies of the same to every company, firm or person in the state eligible to membership; with a letter inviting them to become members of the association as organized. It is expected that this association will develop into one of the largest state associations in the country. There is a sufficient number of local companies in Illinois to supply the material.

THE COPPER TARIFF.—THE PETITION OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION FOR THE ABOLITION OF DUTIES.

The committee appointed at the last meeting of the National Electric Light Association to petition the proper committee of Congress for the abolition of duty on copper, appeared at Washington, January 16, through Mr. Phelps, who presented the following petition to the Committee of Ways and Means, with the subjoined address.

Petition to the Honorable Committee on Ways and Means, House of Representatives, U. S. A.

The subscribers were appointed a committee to petition your honorable body for the abolition of duty on copper ingot, plate, bars, rod and wire. We represent the National Electric Light Association, a body composed of representatives of electric lighting companies throughout the United States, and also of manufacturers of and dealers in electric lighting apparatus and supplies.

The resolution appointing this committee was passed without a dissenting voice. We, therefore, have the honor to present this petition, earnestly requesting that the action asked be taken as a measure which will be approved by the great body of users and manufacturers of copper.

(Signed) CHARLES A. BROWN,
GEORGE M. PHELPS,
J. F. MORRISON.

The National Electric Light Association consists of corporations, firms and individuals owning and operating stations and plants for the distribution of light and power by electricity.

At the time of the last convention of the Association, August 6, 1889, the capital then invested in the industries above named was estimated, from statistics collected by the secretary of the Association, to be no less than $275,000,000. That sum represented mainly electrical apparatus and electric conductors for the supply of 238,000 arc lamps and 2,700,000 incandescent lamps, in all which apparatus and conductors copper is an indispensable and chief material. In the total cost of electric plant for light and power distribution, it is estimated, by competent experts, that from one-fourth to one-third is expended for copper.

The foregoing figures and statements sufficiently indicate the magnitude of the interest of electric light and power companies in the price of copper.

In the opinion of the petitioners the proposed abolition of the copper tariff does not touch the question of protection to American industry. The duty on copper appears to be wholly superfluous as a protection to American producers of that metal. The United States not only produces more copper than it consumes, and consequently exports that metal, but it possesses the richest and most easily worked copper mines in the world, and its mining companies produce the metal and put it in the market at a lower cost than is possible to the Spanish or Chilian miners. Obviously the American producers of copper require no duty to protect their domestic market; and their exports of copper furnish sufficient evidence of their ability to meet competition in foreign markets.

The existing duty is of no appreciable value to the national treasury, because copper is not imported in any considerable quantity. As a source of national revenue the copper tariff is practically useless, and the returns from it could not be increased materially under the conditions of production throughout the world by any modification of the rate of duty, if the government needed increased revenue, which it confessedly does not.

It would appear, therefore, that the duty on copper can only be efficient, in enabling the mining companies and dealers in copper to establish and maintain excessive prices through combination for that purpose. It is believed that the United States duty of four cents per pound was a considerable factor in the operations of the syndicate established in France in the autumn of 1887, and which syndicate, aided by its agreements and contracts with copper mining companies in this country, succeeded in controlling the copper production and markets of the world for more than a year, doubling, for a considerable period, in London and New York, the price existing just previous to the beginning of its operations. This was effected, moreover, in the face of an abundant supply of the metal. For some months after the breakdown of the French speculation, the American companies maintained the price in this country considerably in excess of that of European markets.

Touching the relation of the duty on copper to combinations for maintaining excessive prices, the following quotation is subjoined:—

Extracts from Editorial in New York *Tribune*, May 15, 1889.

The mine owners have publicly stated that they are able to produce more than all the copper this country consumes, and a large part of it at a cost not exceeding six cents per pound, and that they propose to the French bankers, who hold an enormous unsold stock to fix the selling price at about thirteen cents per pound—more than double the cost. Nothing need be said about the right of the producer to get a profit of more than 100 per cent. on his copper, provided he is not a beneficiary of a national policy intended to protect and encourage American production. But the mine owners are beneficiaries of that policy, and owe to the public a certain consideration and service in return. If they enter into a combination for the benefit of foreign speculators and bankers against the interests of American producers, the duty on copper may not last long. * * * There will in all probability be a revision of the tariff next winter. The party in power being anxious to defend all industries that need and merit defense, will for that very reason be more strongly pressed to cut off duties where no defense appears to be needed or where it seems to be not deserved. Combinations of speculators to corner the markets of the world are not highly popular, and will not appear to members of Congress to merit particularly favorable consideration. Under such circumstances the demand for a removal of all duties on copper ore, pig and bars, will be difficult to resist. It is safe to say that, had the Mills bill proposed no change more unpopular or unobjectionable than that, its public support would have been incomparably greater.

In short, and to recapitulate, in the opinion of the National Electric Light Association the duty on copper, being useless for revenue and unnecessary for protection, should not be suffered to remain on the statute books of the United States, since its only remaining function is to serve as an ally to the promoters of combinations for putting up prices, a process to which the government should not lend its assistance.

HOW TO BUILD A POLE LINE.

Mr. George F. Card, superintendent of the Cincinnati Electric Light Co., is building an overhead circuit that can be profitably copied by all new companies. Selected white oak hexagonal poles, that rise 40 feet clear of the sidewalk, are placed in narrow lodes 6 feet in depth, and the vacant space is filled in—not with dirt, but entirely with macadam. Wherever the solid stone flagging covers a section of the basement, no hole is made, other than four bolt holes, by means of which a tapering cast-iron thimble 4 feet in height and weighing 600 pounds is securely bolted to the sidewalk. The pole is placed within the thimble and the surrounding space filled with melted sulphur, which allows for any change of temperature as well as preventing the absorption of moisture. Thimble and pole are painted with two coats of a neat red color to a height of 6 feet, then a 12-inch band of black, and the remainder clear white. Heavy cross-arms having four, six or eight holes are used, double arms are placed at each turning point, while every cross-arm is double braced, and every corner pole strongly guyed with ⅜ inch galvanized steel rope and swivel turn buckle to a 10-foot oak post placed at an angle 8 feet in the ground. The pins are of split oak, the corner pins being bolted to the cross-arm, and all glass insulators are of the heavy double-petticoat deep groove form. No. 6 Simplex heavily insulated wire is now being strung, and where it comes nearer than 3 feet below the telegraph or telephone wires the latter are raised to the proper height, the respective company furnishing the poles and material and Mr. Card the necessary labor. General Hickenlooper instructed Mr. Card to spare no expense in constructing a strong, well-built line, of the best material that money will buy, in order that the company could once for all determine whether overhead circuits could be safely and economically operated, irrespective of what others may claim. Mr. Card said, in referring to underground systems: "In a short time we shall be carrying on a series of experiments to determine the best method of underground work, and we are perfectly willing and stand ready to place our wires underground the moment a safe, practical method is demonstrated." This overhead pole line is so perfectly constructed and so neat in appearance that the Board of Public Works approved the following report and recommendation: "The Committee on Light recommends that in the matter of erecting electric light poles on Fourth street the Cincinnati Electric Light Co. be authorized to proceed with the erection of poles under their permit and the ordinances, and that when said line of poles is erected, the Brush company be required to remove the poles now on Fourth street, and to occupy the line of poles of the Cincinnati Electric Light Co."—*Electrical World*, Feb. 1.

A WENSTROM DYNAMO TESTED AT JOHNS HOPKINS UNIVERSITY.

We have received a report of a series of tests of a Wenstrom dynamo, recently conducted at Johns Hopkins University, by Dr. G. A. Liebig, Dr. Louis Duncan and Mr. W. F. Hasson.

The dynamo was described by the manufacturers as an 800-light machine and was stated to absorb energy, when doing full duty, at the rate of about 60 h. p.

The following table gives the results of the several determinations :—

Current.	E. M. F.	Horse-power.	Dynamometer horse-power.	Loss. Δ	Losses, Friction, Reversals, etc.	Losses, Current^2 × Resistance.	Efficiency.
134.8	114.0	20.6	24.97	4.4	4.4	.17	82.5
194.1	115.6	30.1	35.3	5.2	4.5	.38	85.2
371.6	98.3	49.0	54.5	5.5	3.5	1.30	89.9
400.0	110.0	58.9	64.7	5.8	4.1	1.50	91.0

Speed of dynamo, "330" revolutions per minute.

A DINNER TO MR. E. H. JOHNSON.

A complimentary dinner was given by Mr. H. McL. Harding and Mr. J. L. Barclay, of the Sprague Electric Railway and Motor Co., to their former president, Mr. Edward H. Johnson, at the Hoffman House, Monday evening, January 20. A number of the gentlemen who had been Mr. Johnson's associates with the Sprague and with the Edison companies were present, including Honorable John H. Wise, Samuel Insull, J. H. Vail, S. Dana Green, H. W. Blake, F. J. Sprague, J. K. Muir, Frank Johnson, T. C. Martin, C. W. Price. Much good-fellowship prevailed, and all the gentlemen, in responding to toasts, expressed their esteem and respect for Mr. Johnson in flattering terms. Mr. Vail presented a series of complimentary resolutions on behalf of Mr. Johnson's associates and the employés of the Sprague company.

OBITUARY.

Austin Goodyear Day.

The death of Mr. A. G. Day, at South Poland, Me., December 28, last, takes from electrical manufacturing and trade circles one of their best known figures. Mr. Day was born in West Springfield, Mass., November 24, 1824. At the age of sixteen, with his cousin, Charles Goodyear,—who afterwards acquired fame and fortune in the india-rubber business,—he visited Northampton, where he first saw the process of manufacturing india-rubber goods. This incident determined his pursuit for life. Captivated with the business he soon went into Mr. Goodyear's service as correspondent and bookkeeper at his factory at Woburn, Mass.

Much of his time was spent in the study of india-rubber—its physical and chemical qualities, and the processes of its manufacture. He assisted in the vulcanization of the first two or three yards of sheet-rubber already being treated by Hayward for Goodyear.

He continued for several years in the service of Mr. Goodyear, instructing the workmen in the various factories set up, and conducting experiments in applying the process of vulcanizing to numerous articles. At the Roxbury factory he made the acquaintance of Professor Hayes, afterwards state assayer for Massachusetts, which proved of great value to him. It was under the general directions, and often the close inspection of the professor, that Mr. Day now prosecuted many of his experiments, with new ardor, with a view of discovering a substitute for sulphur. Although this object was not attained, his long and varied course of experiments, under the suggestions of Professor Hayes, were of the highest importance in their bearing upon his later discoveries.

It was during his experiments under Professor Hayes, in 1845, while vulcanizing rubber in melted sulphur, that he made many pieces of rubber of a hardness like horn.

In 1854 Mr. Day bought a factory in Seymour, Conn., where his manufacturing has since been continued without interruption. He early gave attention to the production of insulated wires and cables for the telegraph service, a branch of manufacture which, in recent years, has developed into the manufacture of a great variety of electric conductors, to meet the requirements of electric light and power distribution. Mr. Day's "kerite" insulation has made its way into all fields of electric work.

Long ago Mr. Day's health was impaired by excessive devotion to work and experimentation. Not long since he retured from an absence of some six years in Europe, whither he went for needed rest and recuperation.

SHIPS STRUCK BY LIGHTNING.

Up to 1820, when Sir W. Snow Harris commenced his agitation for the use of lightning conductors at sea, ships had practically been without any such protection. It is, therefore, not surprising to find, that in the course of about fifty years—from 1793 to 1840—over 200 ships had been struck by lightning. Between 1810 and 1815 the Royal Navy suffered severely, for damage was done by lightning to no fewer than 35 line of battle ships, 13 frigates, and 10 sloops. It was estimated that in 22 years from 1793 to 1815—the spars of all kinds shattered by lightning and rendered useless were worth about £72,000. In 1813 no fewer than five out of thirteen line of battle ships cruising off the Rhone were struck by lightning on the same night. In some of the old warships an unsuspected source of danger was often to be found. A capstan, having an iron spindle five feet long and six inches in diameter, was placed vertically over the magazine, immediately under which were long metallic bolts used in the construction of the ship, which passed through the keel into the sea. No arrangement could have been better provided to ensure an explosion. The Harris system of conductors entirely superseded the obsolete chains of Dr. Watson, which stretched from truck to water line when in use, but were more often stowed away. The following are a few instances of the damage caused by lightning to the old badly-protected wooden ships. In April, 1827, the American packet ship "New York," bound to Liverpool from New York, was struck when about 500 miles from the nearest American land. Her old-fashioned conductor was not aloft when she was first struck. Her conductor was then placed in position. It was composed of an iron terminal rod standing up from the royal truck about four feet, to which was attached an iron chain, which trailed in the sea. Again she was struck, and this time the conductor was fused and set the deck on fire, although at the time the rain was falling in torrents. In 1845 a Turkish vessel in the Baltic was struck. Her conductor was aloft, but was not in connection with the sea. A hole, similar to that made by a cannon ball, was made in her side. In 1820, the French corvette "Coquin" had a hole made in her bottom by a stroke of lightning in the Bay of Naples, and but for ready aid must have sunk at her anchors. Finally, the 74 gun ship "Cumberland" required three complete refits and two new mainmasts in the short space of 18 months owing to being repeatedly struck by lightning.—*Electrician* (London).

DEEP-SEA FISHING BY MEANS OF THE ELECTRIC LIGHT.

In the investigations that were undertaken by the Prince of Monaco, in deep-sea soundings an ingenious method was adopted to obtain specimens of the living creatures existing at the bottom of the ocean. The apparatus used was shown at the Paris exhibition. The cage in which the submarine animals were caught, according to *Le Genie Civil*, consisted of a cylinder of wire having three conical entrances, like those of a lobster pot, and weighted for submersion with detachable weights. It was, however, very unlikely that at these immense depths, where the darkness is practically total, any fish would voluntarily find their way into the trap, and steps were taken to attract them by a light placed nside it. Obviously, no light was available but an electric light; but to get an electric light to burn a mile or two under water was not easy. The only resource was to supply the incandescent wire from a battery in the trap. Here, however, another difficulty appeared. It was necessary to enclose the battery, which had to be of considerable power, in a box of some kind, and as the hydrostatic pressure at such depths was six or seven hundred pounds per square inch, it was found impossible to make a box which was not crushed before it reached its destination. At last, however, this trouble was overcome by the curious device of connecting the box with a balloon. The balloon was made of cloth dipped in india-rubber, and so arranged that the air in it was in communication with that in the battery box. On sinking the apparatus, the hydrostatic pressure, being virtually uniform all round the balloon, compressed it equally on all sides, forcing the air out of it into the battery box, until the pressure inside the box and balloon exactly balanced the pressure outside. This process went on to any extent, so that at the bottom of the sea, although the balloon was reduced by the enormous force exerted on it to a small fraction of its original size, it still kept the internal and external pressures equal. On raising the apparatus again it expanded as the pressure diminished, and brought the battery box to the surface uninjured. So successful was this device, that, not content with capturing deep sea fish, the Prince and his assistants propose on their next expedition to send down a photographic apparatus and bring back negatives of the bottom of the ocean, as seen by the electric light.—*Electrician* (London).

... ALTHOUGH it seems easy it is really not very easy to get into the way of using the centimeter (about two-fifths of an inch) as the unit of length.—*John Perry.*

CLUB NOTES.

New York Electric Club.—A Lecture by Professor Cross.

The monthly meetings of the Electric Club, during the fall and winter, have steadily increased in attendance and interest. The meeting January 16 was one of the most enjoyable of the year. The lecturer was Professor Chas. R. Cross, Professor of Physics in the Massachusetts Institute of Technology. The parlors of the club were filled by an appreciative and representative audience. The title of the lecture was the "Acoustic Principles Underlying the Art of Telephony," and set forth the several elements of the topic with completeness and entire lucidity.

Professor Cross is gifted with the ability to deliver an address or lecture untrammeled by manuscript or even notes, and he does it with no loss of clearness or continuity. The lecture was illustrated by apparatus brought from Boston. The lecture was followed by an interesting discussion, in which Professor Geo. Forbes, of London; Professor Le Conte Stevens, of Packer Collegiate Institute, Brooklyn; W. D. Sargent, John J. Carty, Thos. D. Lockwood, A. V. Garratt and others, took part. Professor Cross closed the discussion with some interesting references to the experiments of Helmholtz. A unanimous vote of thanks to the lecturer was given with enthusiasm before adjournment.

At the opening of the meeting, President O. E. Madden in the chair, some of the business matters of the club were presented. After the reading of the minutes of the previous meeting, which the secretary presented in rhyme, the president made a comprehensive statement concerning the financial condition of the club. His address was listened to very attentively, the whimsically entertaining manner in which he presented facts and figures causing several interruptions from enthusiastic applause.

President Madden said he was delighted at the large attendance of members and friends, and he took it not only as a fitting compliment to Professor Cross, who had come at great inconvenience to himself from Boston to interest and instruct; but he took it also as an evidence of the interest in the objects for which the Electric Club was established, and this argued well for its future prosperity and success. Continuing, he said: "Since the last regular meeting of the club, I have been called to the office of president by your board of managers, to fill the vacancy caused by the resignation of Mr. Gilliland. I am not unmindful of the honor thus conferred upon me, nor lacking in appreciation of the responsibility of the position. It shall be my aim and endeavor to advance the interests of the club in every way to the best of my ability. In this, however, I cannot hope for the greatest success unless I am assured of the co-operation of each and every member of the club, which I sincerely trust will be accorded to me."

The president then presented a statement of the club's financial affairs. While the showing, he said, indicated that the club needed, and would continue to need, the aid of its members, it proved that the club's finances were in much better condition than at any previous time, and expressed a very strong hope of being able soon to wipe out the floating debt, and at the same time to reduce the bonded debt.

Letters were read from the Sawyer-Man Electric Company, P. H. Alexander, general manager, and the United Edison Manufacturing Company, H. Ward Leonard, general manager, forgiving in each case the amount of their bills for labor and fixtures furnished the Electric Club, and each letter containing earnest wishes for the success of the club. The letters were received with hearty applause.

A cable message was also read from ex-president Henry C. Davis, of the club, who is now in London, in which he wished the club every success and accepted the proposition of the finance committee in settlement of his bill against the club for moneys advanced at the time the club house was fitted up, President Madden stating that General Manager G. G. Ward, of the Commercial Cable Company, had very kindly made no charge for the use of his line in sending and receiving messages. Attention was called to the fact that in several cases bondholders had signified their interest in the club by presenting the finance committee with their present holding of bonds, and that the first lot received was from the club's most distant member, John I. Sabin, of San Francisco, who presented the club with $250, accompanied by his best wishes, and this example the president thought it was hardly necessary to dwell upon.

After the adjournment of the formal meeting, an appetizing lunch, accompanied by Electric Club punch, was set out in the back parlor, and the 150 or more members and visitors present enjoyed a social re-union around the table. Music by Mr. W. S. Hine and Lieutenant F. W. Toppan, U. S. N., and recitations by Mr. John C. Tomlinson and Mr. Walter Pelham, added to the pleasures of the evening. It was the unanimous expression of the very large number present, that the meeting was one of the most agreeable in the history of the club.

Among those from a distance who were present were Professor Geo. Forbes and Sir John Swinburne, of London; Professor Le Conte Stevens, Brooklyn; F. W. Webster, T. D. Lockwood and C. J. H. Woodbury, of Boston; R. K. Steen, Wilmington, Del.; A. E. Powers and J. A. Powers, Troy, N. Y.

Among those from New York were C. O. Baker, Jr., Gen. C. H. Barney, G. B. Coggeshall, J. C. Chamberlain, E. A. Colby, E. W. Carritt, W. M. Clark, J. J. Carty, F. Gottschalk, M. W. Garver, A. V. Garratt, A. S. Hibbard, H. P. Hungerford, W. S. Hine, E. J. Hall, Jr., E. A. Leslie, O. E. Madden, H. B. Miller, F. C. Mason, F. C. Maguire, A. H. Patterson, E. F. Peck, W. S. Perry, J. C. Reilly, J. A. Seely, W. D. Sargent, H. L. Storke, J. H. Seymour, Lieutenant F. W. Toppan, J. C. Tomlinson, Dr. S. S. Wheeler, George Worthington, Jesse H. Bunnell, Jos. Wetzler.

A number of the officers and members of the American Society of Civil Engineers, which was in session in New York, were present by invitation, and were made at home by the members of the club. Among these were W. G. Worthen, of New York, and James B. Francis, of Lowell, both past-presidents of the society.

It was announced that the next regular meeting would be February 20th, at which time Honorable Grosvenor P. Lowrey, would deliver an address on "Patent Law, and What Constitutes an Invention."

Boston Electric Club.

The fourth annual dinner of the Boston Electric Club occurred January 6, at Young's Hotel, the new president, H. B. Cram, in the chair. In the after-dinner discussion, President Cram said he hoped, by free discussion and intelligent decision, to relieve the public mind from fear and anxieties which may arise in regard to the transmission of electrical energy. W. J. Denver, of the New England Telephone Co., said he was glad more attention will be paid to the discussion of electrical matters during the coming season. A great deal of talk will be made on Beacon Hill during the present session about electrical matters, which the average legislator but little understands. Efforts will be made to show how wires should be constructed and regulated, so as to be entirely safe. My idea is, he said, that the better way to do would be to allow that business to go as in the past, unhampered. If a sensible code of rules can be formulated we will all be willing to co-operate in any direction that is necessary in regard to safeguards. I have some appreciation of the tendencies to make injudicious laws.

Frank Ridlon said that the Boston Electric Club ought to be the instructor of the public of Boston on electrical matters in the future. We want no uninformed legislation, said he, but we do want legislation based on information.

W. A. Stiles, of the Thomson-Houston company, said:—"Whether justified or not, there is a general impression that the electric current going through the wires of the United States is not quite safe or comfortable." He suggested that it would be a good idea to ask the police and fire commissioners to a conference, and explain how, by the use of insulated pliers and rubber gloves, blockades of horse cars and possible injury to horses and perhaps men might be prevented.

Arthur Lord, of the Massachusetts civil service commission, thought there is a danger in too much legislation. He said that much of the success of electrical operations in the past has been due to the absence of restrictive legislation. If there is to be legislation it should be wisely considered, and should receive the approval of the men who have as much interest in the matter as any other members of the community.

Roman I. Zuboff, of Russia, said that Russia acknowledges its debt to America in electricity. One of the foremost electricians in Russia is a student of American electrical matters, and he lately proposed to the Czar an elevated electrical railroad from St. Petersburgh to Zaretzin, a distance of 2,000 miles.

George F. Meech, G. W. Mansfield and Dr. A. F. Mason spoke on the necessity for more education of the public mind on the question of electricity.

MANUFACTURING AND TRADE NOTES.

The Westinghouse Machine Company, of Pittsburgh, has received an order through its agency at Copenhagen, Denmark, for one of its now famous automatic compound engines. The size selected is 14 & 24 x 14, and it will be used at Kopparbergs Bergslaget at Falur, near Stockholm, Sweden. Large numbers of these engines are now being shipped to foreign countries.

Mr. John R. Tilley, who for several years past has represented British builders of machinery and steam engines at Demerara, British Guiana, has severed his British and Scotch engine connections, and has become the resident agent of the Westinghouse Machine Company, of Pittsburgh, for Demerara and the British West Indies.

Messrs. James Leffel & Co., Springfield, O., manufacturers of the celebrated "Old Reliable" water-wheel, and superior steam engines and boilers, have enjoyed a large trade throughout the season of 1889, and carry many orders over into the new year. They are now running their works until 10 o'clock at night in order to meet the steadily increasing demand for their specialties.

"**Cleverly**," 1018 Chestnut street, Philadelphia, adds to his line of electrical apparatus for domestic uses, including call-bells, annunciators and gas lighting appliances, a "pendant burner," having a double lift-over electrode, which is claimed to increase the efficiency and economy of electric gas lighting and to avoid short circuiting.

Mr. D. H. Edgerton, of Philadelphia, has established and equipped a shop and laboratory for electrical experimentation, at 805 Sansom street, equipped with facilities for careful investigation, as well as for manufacture and repair. Mr. Edgerton has under his control, at his place, both high and low tension direct currents, and the alternating current, covering a range and variety of current supply for electrical work sufficient for all ordinary demands of experimentation. Mr. Edgerton is well known as a manufacturer of motors.

The Riker Electric Motor Co., manufacturers of dynamos, motors and specialties in motors, 45 and 47 York street, Brooklyn, N. Y., call attention to their latest type of dynamos and motors. The Riker machines have been well known for a long time, and in the new type simplicity of mechanical device and construction, with diminished cost of manufacture have been sought. The Riker company particularly point out the low armature bearing, insuring minimum vibration and diminished noise in running, the distribution and fine grade of iron used, and the distinctiveness and general beauty of design.

The Okonite Co., New York, with its usual enterprise will be on hand at the electric light convention at Kansas City, showing a full line of its "Okonite" wires, cables and tapes. The watchword of this concern is "Forward" and their business activity and position in the electrical trade shows it to be thoroughly lived up to.

The Standard Underground Cable Company's annual meeting of stockholders was held in Pittsburgh, January 23d, and a meeting of directors on the succeeding day. All the old officers were re-elected, viz:—George Westinghouse, Jr., president; C. H. Jackson, vice-president and general manager; John H. Dalzell, treasurer; J. W. Marsh, secretary; Elmer L. White, auditor and assistant treasurer. The following directors were elected:—George Westinghouse, Jr.; Robert J. Pitcairn, Caleb H. Jackson, Mark W. Watson, John H. Dalzell, Joseph W. Marsh, Henry Snyder.

A very favorable report of the year's business was submitted, indicating a net profit of 11 per cent. on the par value of the capital stock. The company starts upon the new year with orders in hand aggregating nearly $150,000. A dividend is announced for April 1st.

Messrs. Garvin & Co. have recently introduced a new die grinder, designed particularly for use in connection with punch presses for grinding and sharpening dies, punches, etc., and for general use as a small surface grinder. The slide is traversed by hand by means of a lever, making a simple machine. The spindle has a vertical screw adjustment, and ample room is provided for running wheels of large diameter. The plan of belting this machine puts a loop in belt, which allows belting direct and dispenses with a tightener. The table has a transverse screw adjustment, and is provided with T slot for holding work. Surface can be ground at one setting, 6 inches by 6 inches. The machine weighs complete 350 pounds.

ELECTRIC STREET RAILWAYS.

Boston:—President Henry M. Whitney, in speaking of the plans of the West End Street Railway Co., says that the company has bought the property in Cambridge of the New England Glass Co., where it intends to place its power plant for the operation of electric cars in Cambridge, Charlestown and Somerville. The property is well adapted for immediate use, as there is a large chimney sufficient for 6,000 or 7,000 h. p., buildings suitable for engines and boilers, and a wharf for landing coal. The company has already contracted for about 2,000 h. p. in engines to be placed in this power house, which will be sufficient for immediate needs, and hopes to have the plant in operation early in the summer.

The directors have recently authorized the purchase of 200 open cars, thereby adding nearly 25 per cent. to the open car equipment, and are expecting to contract for a large number of additional box cars, to be ready for another winter. The growth of the passenger business is so rapid that it is difficult for the company to provide equipment rapidly enough to meet the demand. The number of passengers carried per day averaged for each day in December nearly 50,000 a day more than in 1887.

"So far as I am able to judge from expressions of opinion by all communities that are now reached by the electric cars," said Mr. Whitney, "the electric system is giving excellent satisfaction, and we are solicited to extend the system from all quarters. The lines from Park Square to South Boston and from Egleston Square to Forest Hills will be among the first to be equipped the coming year. The Egleston Square line itself will probably be opened between this and the 1st of February."

These statements by President Whitney show that the company is making great preparations to meet the extraordinary increase of business, and when the new tracks are laid and the electric system is extended the public will be able to judge fairly in regard to the merits of the system. It is said that the plan which the directors of the road have in view for the relief of travel in the crowded streets of the city proper is an elevated railroad—a scheme which has in the past met strong opposition.

The Thomson-Houston Electric Co.'s railway list of December 15, 1889, shows on that date 47 street railways in operation, equipped with their system, comprising 335.75 miles of track and 525 motor cars; in addition three Thomson-Houston cars were running on roads equipped with other systems.

At the same date the Thomson-Houston Company had under construction or contract, 34 roads with 451 miles of track and 511 motor cars. They had in hand orders from roads then in operation for additional equipment as follows:—25 motor trucks and 90 motors.

The Sprague Electric Railway and Motor Co. report the following recent orders for street railway equipment:—Davenport, Ia., Davenport Electric Street Railway Co., 4 cars; Dubuque, Ia., Electric Light and Power Co., 10 cars; Chicago, Ill., Cicero and Proviso Street Railway, 12 cars.

They report also the following additional orders from street railway companies already equipped with Sprague or other systems:—Sioux City, Ia., Sioux City Electric Railway, 3 cars; Milwaukee, Wis., West Side Street Railway, 9 cars; Des Moines, Ia., Des Moines Electric Railway, 2 cars.

The Sprague company has made several contracts to supply its motors and railway apparatus for use in foreign cities. Now comes a contract for a railway in Japan. Through arrangements made by its agents in that country, Messrs. Everett, Frazar & Co., the Sprague company has already commenced construction upon a railway line in Tokio, and it will not be long before the road will be in operation. The first shipment to this distant point includes two electric cars, fully equipped with Sprague apparatus, with full station and line equipment for a complete installation. It is said that this shipment will soon be followed by other and more extensive shipments, and that an extensive street railway line will at no distant day be in operation in Tokio on the Sprague system.

The Sprague Electric Railway at Moline, Ill., is now in successful operation.

Chicago capitalists are negotiating for the purchase of the Belle City street railway, of Racine, Wis. If it is bought, electric motors will be substituted for horses.

A contract has recently been closed for an electric railway at San Jose, Cal., which is the first Thomson-Houston road in the state. One electric railway has already failed in that city. The Thomson-Houston Electric Co. will introduce its latest and most improved apparatus. Ornamental double bracket iron poles will be used, and nothing will be left undone to make the road a model one in every respect.

ELECTRIC LIGHT AND POWER.

The Lafayette Car Co. has decided to install an electric lighting plant for the illumination of their extensive buildings and yards at Lafayette, Indiana. The order was placed with the Heisler Electric Light Co., of St. Louis, and prompt shipment required. The apparatus was shipped from St. Louis on the day following the receipt of the order.

The Rawson and Root Lumber Co., of Michigan City, Ind., which has been operating a Heisler electric lighting plant for about a year, has contracted to furnish a large number of lights to the furniture manufacturers, whose works are run in connection with the Northern Indiana State Prison. To carry out this contract, an order has been placed with the Heisler Electric Light Co., of St. Louis, for one of their largest dynamos, with the necessary lamps, sockets, etc. The new apparatus is to be in operation before the middle of November.

The Westinghouse Electric Company will remove its works from Pittsburgh. It will erect, as soon as possible, new and much larger factories near Brinton, on the main line of the Pennsylvania Railroad, about twelve miles from Pittsburgh.

This removal is deemed advisable by the directors of the company on account of lack of sufficient space in the present works, and the great cost of enlarging the premises now situated in the heart of the city. The present buildings are to be sold and will, it is thought, yield $500,000. This money will be used in the construction of the new shops, which will occupy a plot of fifteen acres. It is the purpose of the Westinghouse Electric Company to lay out and build up a new borough surrounding the plant, as is being done at Wilmerding, several miles distant, where the new Westinghouse air-brake works are nearing completion. The Electric company since a year ago has increased the number of its workmen from 600 to 1,300, and these, with their families, will give the new town a population of about 5,000. The new town will have connections with the Pennsylvania and with the Vanderbilt systems of railroads.

The record of the progress of the Westinghouse Electric Company during the year 1889 is very remarkable, even in these days of astonishing developments in electrical industries. On the first of January, 1889, 132 central station plants had been sold by the company, aggregating a capacity of 240,000 lamps. The number of central station plants has now reached 266, with an aggregate capacity of nearly 500,000 lamps.

Meantime the absorption of the Waterhouse arc light business, the manufacture of the Shallenberger alternate current meter, Tesla motor work, and other additions to the original undertaking, compelled large additions to the Pittsburgh shops and the removal of the lamp factory to New York. The number of employés at Pittsburgh grew from 600 to 1,400. Available space being now exhausted the company wisely adopts, for the removal of its works, a suburban locality which will permit of indefinite expansion of factory room in the future.

The Ocean Grove Camp Meeting Association (Ocean Grove, N. J.), have arranged to greatly enlarge their electric lighting plant between now and next spring, and have contracted with the Heisler Electric Light Co., of St. Louis, for two of their largest dynamos. The previous orders of this association covered four Heisler dynamos.

The New York, Lake Erie and Western Railway Co. has introduced electric motors in place of mules for traction purposes in its mines. An electric motor has been set at work in the company's Hillsdale coal mine, near Forest City, Pa. It is stated that the motor will make the round trip from the coal breaks to the breaker in six minutes, hauling 30 cars. It required nine mules to draw the train at one-quarter the speed. By using the electric motor the company saves $25 per day on the cost of power, and is enabled to increase the output of the mine from 1,000 to 1,500 tons per day.

Mr. Charles Heisler, the founder of the Heisler long-distance lighting system, has recently returned to St. Louis from Paris much gratified by his success in carrying off a gold medal from the Jury of the Exposition of last year. He is much improved in health, but not yet ready to re-enter active business.

The Thomson-Houston Electric Co. report the following sales, with the number of lights in each case.

Incandescent apparatus for central stations :—

Franklin, Tenn., 300; Northampton, Mass., 650; Chatham, N. Y., 650; Beverly, Mass., 650; Great Falls, N. H., 1,300; Punxsatawney, Pa., 650; Sandy Hill, N. Y., 650; Petulama, Cal., 650; Muscatine, Ia., 650; Battle Creek, Mich., 650; Langhorne, Pa., 500: Belfast, Me., 300; Auburn, N. Y., 1,300; Meriden, Conn., 1,300; Paris, Ky., 1,300; Loug Branch, N. J., 650; Jacksonville, Fla., 650; Wallace, Idaho, 650; Millbury, Mass., 650; Brandon, Vt., 650; Butte, Mont., 650; Springfield, Ill., 650; Fresno, Cal., 650; Nashville, Tenn., 2,600; Ann Arbor, Mich., 650; Watsonville, Cal., 300; Mt. Clemens, Mich., 650; Bozeman, Mont., 500; Spokane Falls, W., 300; Great Falls, Mont., 650.

Arc apparatus for central stations :—

Franklin, Tenn., 20; Butte, Mont., 30; Rochester, N. Y., 105; Kokoma, Ind., 70; Bedford, Ind., 50; Long Branch, N. J., 100; Wilkesbarre, Pa., 50; Lowell, Mass., 25; Atlanta, Ga., 50; W. Superior, Wis., 50; Martin's Ferry, Ohio, 20; Johnstown, Pa., 50: Hyde Park, Mass., 50; Spokane Falls, W., 50; Petulama, Cal., 50; Omaha, Neb., 100; Denver, Col., 70; Richmond. Mo., 15; Joliet, Ill., 35; Nashville, Tenn., 300; Mt. Clemens, Mich., 30; Cheboygan, Mich., 30; Bluffton, Ind., 50.

Arc apparatus for isolated plants :—

Mayfield Woolen Mills, Mayfield, Ky., 200; Western Kentucky Lunatic Asylum, Hopkinsville, Ky., 300; W. Russell & Co., Bellows Falls, Vt., 50; L. C. Bass Mfg. Co., Guilford, Me., 100; Portland Steam Packet Co., Portland, Me., 400; Wayside Knitting Co., Troy, N. Y., 200; Carrollton Furniture Co., Carrollton, Ky., 150; Morgan Envelope Co., Springfield, Mass., 100; Cambridge Training School, Cambridge, Mass., 200: American Net & Wire Co., Cambridge, Mass., 200.

Incandescent apparatus for isolated plants :—

Maryland Pavement Co., Baltimore, Md., 9: Alliance Street Railway Co., Alliance, O., 50; Philadelphia & Reading Coal and Iron Co., Pottsville, Pa., 30; St. Paul Foundry Co., St. Paul, Minn., 9.

At Newport, R. I., the Jarvis Engineering Co., of Boston, are actively engaged in the alteration and enlargement of the plant of the Edison Illuminating Co., of that city. This company, since its organization, has met with remarkable success. Their new plant, as enlarged, has been designed by Mr. John Whipple, Jr., general superintendent, with a special view to the most economical production of the steam power. The steam battery consists of four horizontal tubular boilers, set with the Jarvis patent furnace to burn the cheap grades of fuel. Power for the dynamos is supplied by eight Armington & Sims engines, of their improved pattern, aggregating 850 h. p., and, by direct belting, saving the expense and loss of power from the use of shafting. The exhaust steam from the engines is passed through a National heater, and utilized to heat the feed water before it enters the boilers up to a temperature of 212 degrees.

The Suburban Light and Power Co., of Boston, which has been awarded the contract for the city lighting, has leased the building on Howard street, Roxbury, formerly used by the Globe Nail Works as a rolling mill. It is of brick, 175 x 76 feet, and contains a 600 h. p. engine. The company's contract with the city calls for about 800 lights, and this building is said to be ample to accommodate machinery and apparatus far in excess of immediate requirements, and to permit of a large extension of business.

The Beatrice Electric Light Co., Beatrice, Neb., under date of January 6, 1890, issues the following notice :—

"We desire to call your attention to the fact that we have no connection whatever with the 'Beatrice Electric Co.,' nor the 'Beatrice Electric Manufacturing Co.' We are engaged in the arc and incandescent lighting business exclusively, and have no other business whatever.

"We deem this explanation necessary, as some confusion has already arisen from the similarity of names."

The Crocker-Wheeler Electric Motor Co. have put upon the market a complete electric pump; motor and pump being mounted on one frame and connected by spar and pinion gear. The motor is of one-eighth horse-power, and the capacity of the outfit (made for either constant current or constant potential circuits) is given as equal to lifting 1,000 gallons of water per day to a height of 100 feet.

Whipple's Electrical Report for January, 1890, shows a total number of central electric light stations in the United States of 1,265. The number of gas companies given is 981, and of these 237 operate electric light plants in conjunction with their gas business. The number of electric railways in operation or under construction is 162.

The Pennsylvania Railroad Company, having decided to increase the capacity of the electric lighting plant at their main offices in Fourth street, Philadelphia, have shifted their storage batteries to the forward part of the building, in order to utilize the old battery room in the rear for a Corliss engine, to be used as an auxiliary to their present power plant. The Electro-Dynamic Co. has been awarded the contract for making the necessary alterations in the battery plant, switches, wiring, etc. The system will be changed from 60 to 100 volts, the present capacity of the plant being about trebled. The original wiring by the Electro-Dynamic Co., for 1,200 lights, is ample for the additional requirements.

The Edison Down-town Station, Pearl street, New York, destroyed by fire on the morning of January 2d, was rebuilt and running January 13th. To replace the burned station required an immense amount of work, and H. J. Smith, the superintendent, and John I. Beggs, the general manager of the station, got very little sleep while the reconstruction was going on. The old station contained eight dynamos, six being on the first floor of No. 257, and two on the first floor of No. 255 Pearl street. The fire in the buildings broke out at two o'clock in the morning, and at eleven o'clock the same morning Mr. Smith had the auxiliary station in Liberty street, which has a capacity for supplying 5,000 lamps, in full operation. Before the débris in the burned building had become cool, a number of men were put at work, and from that time until the night of January 11th a force of 100 men were at work day and night clearing out the ruins and building a new station.

The building No. 255 was first cleared out down to the cellar. On the floor of the cellar a crib, formed of 14-inch square yellow pine timbers, 28 inches high, was built, one course of timber being laid across the building, and the second course running lengthwise. The interstices between the timbers were filled in with concrete, and on the new flooring thus laid four new engines and eight new dynamos were placed. These have been running at full force since the morning of Monday the 13th. The steam pressure is supplied from the four old boilers in the building No. 257, which, upon examination, were found to be in good condition, although new steam pipes and connections had to be supplied. From this station 19,000 incandescent lamps are now supplied with power. A new flooring was put in at the level of the second floor of No. 255, and ten feet above this a temporary roof has been built.

This station will be used until the company builds its new down-town station, work on which will begin early next spring, to be completed before the end of the year. The new station will be just above the bridge approach, and will be strictly fireproof. It will have a capacity for supplying 100,000 lights, and will furnish power to all the part of the city south of Canal street. The station is planned for 25 engines and 50 dynamos.

THE BRUSH ELECTRIC COMPANY'S STOCK.—The following paragraph was telegraphed from Cleveland, Ohio, January 20, and printed in New York newspapers.

"There was more excitement at the annual meeting of the stockholders of the Brush Electric Company, which was held to-day, than was anticipated by those who held a majority of the shares. Several months ago a controlling interest in the Brush plant was sold to the Thomson-Houston Company, of Boston, but the sale has not been closed entirely. There were 40,000 shares in the company before it was sold, and the Boston corporation bought in all 30,000 of them.

"George W. Stockly, James J. Tracy, Gen. M. D. Leggett, C. F. Brush, and Mrs. John Carr, controlled the Brush company. At the meeting to-day many of the minority stockholders were present with their attorneys. A written protest representing 3,562 shares of stock was presented and spread upon the minutes. It set forth that inasmuch as the majority stockholders had received $25 per share premium for the 30,000 shares sold to the Thomson-Houston company, or $750,000, the "bonus" should be divided pro-rata among all the shareholders.

"The stock is in shares of $50 each, which, at the time of sale, were quoted at $35. Messrs. Stockly, Tracy, and their party sold their holdings to the Boston company at $75 a share. There was considerable discussion among majority and minority stockholders, but no settlement of the controversy was effected."

THE LOWELL ELECTRIC LIGHT CO. will make an extensive rearrangement of their plant. By reason of their contract with the Lowell and Dracut Street Railroad Co. to furnish power for moving street cars, the Electric Light Co. is obliged to seek larger quarters. A lot of land 160 x 300 feet has been purchased, and the company will erect thereon a commodious brick building. Their plant will be arranged by the Thomson & Houston Electric Co. Work will be begun immediately. The location is near the Lowell and Andover section of the Boston & Maine Railroad, which is convenient for the reception of coal. It is favorably situated for the distribution of light and power. By contract with the city and merchants, 530 arc lights are furnished and 600 incandescent. The company's steam plant, now of 1,000 h-p., will be largely increased. The company, originally the Middlesex Electric Light Co., organized under the laws of the State of Maine, absorbed the Lowell Electric Light Co., and about a year ago reorganized under the laws of Massachusetts with the last-mentioned title. W. A. Ingham is president.

THE BRUSH alternating incandescent plant at Barrie, Ont., which has been under construction by Mr. Lawson, of Montreal, for some time past, has been put into operation, and gives such satisfaction that the demand for service has already exceeded the company's expectations, 800 lamps being now connected—some 200 more than originally provided for. The Barrie company has, therefore, ordered additional plant for 1,000 lights. This installation is remarkable as being the only one in Canada using 2,000 volts in the primary wires, which is reduced to 100 on the lamps, Special insulation is used throughout. A water power, five miles from town, drives the dynamos.

LEGAL NOTES.

THE DECREE IN THE DOUBLE-CARBON ARC LAMP CASE OF THE BRUSH ELECTRIC CO. vs. THE FORT WAYNE ELECTRIC LIGHT CO. AND OTHERS.

UNITED STATES CIRCUIT COURT, DISTRICT OF INDIANA.

Present:—Honorable Walter Q. Gresham, Circuit Judge.

The Brush Electric Co. *vs.* The Fort Wayne Electric Light Co., Henry G. Olds, Perry A. Randall and Ranald T. McDonald.	*In Chancery.*

This cause having been brought to a final hearing upon the pleadings and proofs, and having been argued by counsel for the respective parties, and the same having been duly considered by the Court, it is found and hereby ordered, adjudged and decreed by the Court as follows, to wit:—

1. That the following letters patent of the United States, viz.: Letters Patent, No. 219,208, granted to Charles F. Brush, September 2, 1879, for improvement in electric lamps, is a good and valid patent. That said Charles F. Brush was the first and original inventor of the improvements and inventions described and claimed in said Letters Patent, No. 219,208, and that the complainant herein became and is invested with the exclusive right, title and interest in and to said letters patent, as in said bill of complaint alleged.

2. That the said defendants, the Fort Wayne Electric Light Co., Henry G. Olds, Perry A. Randall and Ranald T. McDonald, have infringed said Letters Patent, No. 219,208, granted to the said Charles F. Brush, by manufacturing and selling arc electric lamps embodying the improvements set forth and claimed in the first, second, third, fourth, fifth and sixth claim of the said letters patent, and that said defendants have violated and infringed the exclusive rights of the complainant secured to it by the said letters patent, in the manner set forth and shown in the pleadings and proofs in said cause.

3. That the said complainant is entitled to a discovery and accounting from said defendants of the gains, profits, benefits and advantages had and received by the said defendant, or either of them, as well as an accounting of and for such damages as the said complainant may have sustained through and by the acts of the defendants or either of them, and that the complainant recover said gains, profits, benefits and advantages which the said defendants have received, or which have secured to the said defendants, or either of them, from and by the aforesaid infringement of said Letters Patent, No. 219,208, by the manufacture, use or sale of the improvements therein described and secured by the first, second, third, fourth, fifth and sixth claims thereof, or any of them, and such further damages as the said complainant may have sustained by reason of such infringement.

4. That this cause be referred to W. P. Fishback, a Master in Chancery of this Court, to take proofs and report to the Court an account of the gains, profits, benefits and advantages which the said defendants, or either of them, have received, or which have arisen or accrued to them, or either of them, from infringing the exclusive rights of the said complainant by the manufacture, use or sale of the said improvements, patented in said letters patent, as, or substantially as described and secured, for the first, second, third, fourth, fifth and sixth claims thereof, or any of them; and also to state and report an account of the damages which the said complainant has sustained by said infringement.

5. And it is further ordered, adjudged and decreed that the said Master is hereby authorized to summon the defendants, their agents, employés, before him, as well as the officers and directors of the defendant corporation, and to examine them on oath; and to require the said defendants to produce their books, vouchers and documents touching the matters herein referred to; that the proofs already taken or used in this cause may be used on said reference, and that such other testimony may be taken before the Master, as is authorized by law and the rules of Court, as either party may desire and said Master may direct.

6. And it hereby ordered, adjudged and decreed that the said defendants, the Fort Wayne Electric Light Co., Henry G. Olds, Perry A. Randall and Ranald T. McDonald, together with the officers, successors or assigns, agents, attorneys and employés of the defendant corporation, be, and they hereby are, perpetually enjoined and restrained from making, using, selling or vending any arc electric lamps in which two or more pairs of carbons are independently adjusted and regulated by one and the same regulating mechanism, and are separated and burned successively

to secure the continuous burning of one pair of carbons prior to the establishment of the arc between the other pair, substantially as described in the specification and claimed in the first claim of said Letters Patent, No. 219,208, and also for making, using, selling or vending any electric arc lamps containing the invention, or inventions, substantially as described in the specifications, and claimed in the second, third, fourth, fifth or sixth claims, or any of said claims in said patent, No. 219,208, or any imitation, or substantial equivalent thereof, constructed substantially as described in said specification, and as claimed in that said first, second, third, fourth, fifth or sixth claims, and that an injunction issue forthwith accordingly. And it is further ordered, adjudged and decreed that the defendants pay the cost herein to be taxed, and that the complainant have execution therefor.

(Signed) W. Q. GRESHAM.

January 13, 1890.

BRUSH-SWAN vs. BRUSH.

Judge Coxe of the United States Circuit Court, January 17, filed a decision in the important suit of the Brush-Swan Electric Light Co., of New England, against the Brush Electric Co. The action was brought to compel the specific performance of contracts between the parties and for an injunction and accounting. The Court holds the contracts to have been of such a character that their performance by the defendant cannot be specifically enforced; but the injunction prayed for, restraining the defendant from selling electrical dynamos and apparatus in New England, the territory assigned by the contracts to the complainant, is granted, with a decree for an accounting of the profits.

Judge Coxe adds that the injunction should not interfere with any existing contracts made by defendant with third parties, or restrain the defendant from furnishing supplies and apparatus for established plants.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From December 17, 1889, to January 7, 1890 (inclusive).

Alarms and Signals:—*Watchmen's Electric Time Detector*, H. L. Norton and F. W. Cook, 417,501. *Electric Semaphore Setting Apparatus*, F. Stitzel, 417,525; F. Stitzel and C. Weinedel, 417,526, December 17. *Electric Signal System for Letter Boxes*, G. L. B. Rounseville, 418,322, December 31. *District Telegraph Alarm Box*, C. G. Armstrong, 418,778. *Annunciator*, J. Finck, 418,868. *Electrical Signal-Operating Device*, C. A. Cox and J. F. Cox, 418,910, January 7.

Clocks:—*Time-Distributor for Electric Clocks*, L. H. Spellier, 417,753. *Automatic Electric Clock-Winding Device*, F. A. Lane, 417,927. *Electric Winding Clock*, same, 417,928. *Electric Synchronizing Device for Clock Pendulums*, J. Hamblet, 418,125, December 24. *Electro-Mechanical Time Stamp*, C. A. Randall, 419,068, January 7.

Conductors, Conduits and Insulators:—*Electrical Conductor*, U. H. Balsley, 417,402. *Combined Support and Safety Device for Overhead Conductors*, R. A. Morgan, Jr., 417,497. *Conduit for Electrical Conductors*, J. Tatham, 417,688, December 17. *Underground Electric Conduit*, J. Dell, 417,992, December 24. *Insulating and Waterproofing Composition*, A. E. Menuez, 418,208, December 31. *Bracket for Supporting Electric Conductors*, J. A. Duggan, 418,704. *Support for Electric Conductors*, J. B. Smith, 418,766. *Insulating Nippers*, F. M. Casey, 419,111, January 7.

Distribution:—*System of Electrical Distribution of Currents*, C. J. Van Depoele, 417,654, December 17. *Generation and Distribution of Electric Currents*, F. J. Patten, 418,652. *System of Electrical Distribution*, same, 418,653. *Distribution of Electric Currents*, same, 418,655, December 31. *Distribution of Electricity by Secondary Batteries*, G. B. Prescott, Jr., 418,748. *Method of Transforming and Utilizing Electrical Energy*, M. W. Dewey, 418,912, January 7.

Dynamos and Motors:—*Automatic Regulator for Dynamos*, C. D. Jenney, 417,487, December 17. *Armature for Electrical Machines*, A. Schmid, and N. Tesla, 417,794. *Magneto-Electric Machine*, W. Gillett, 418,120, December 24. *Electro-Magnetic Motor*, N. Tesla, 418,248. *Armature for Dynamos*, J. J. Wood, 418,301. *Automatic Regulator for Dynamo-Electric Machines*, same, 418,302. *Current Regulator for Dynamo-Electric Machines*, same, 418,303. *Electric Motor*, J. J. Patten, 418,654. *Dynamo Electric Generator*, W. Stanley, Jr., 418,659, December 31. *Electric Switch for Motors*, H. H. Blades, 418,678. *Brush-Holder for Dynamos*, P. Claus and E. Gengenbach, 418,685. *Electric Motor or Generator*, I. E. Storey, 418,853. *Electric Motor*, H. B. Niles, 419,059, January 7.

Galvanic Batteries:—*Galvanic Battery*, E. A. Sperry, 417,290. *Treatment of Porous Pots for Electric Batteries*, E. L. Mayer and H Liepmann, 417,392. *Manufacture of Porous Pots for Electric Batteries*, same, 417,436. *Galvanic Dry Element*, C. H. Wolff, 417,458, December 17. *Galvanic Battery*, P. B. Delany, 417,814, December 24. *Battery Carbon*, C. G. Armstrong, 418,837, January 7.

Lamps and Appurtenances:—*Arc Lamp*, J. F. Shawhan, 417,516. *Ceiling Plate for Electric Lights*, H. H. Sawyer, 417,685, December 17. *Incandescent Lamp Socket*, J. W. Packard, 417,787 and 417,788. *Incandescent Electric Lamp*, same, 417,789, December 24. *Combined Gas and Electric Light Fixture*, D. J. Braun, 418,270. *Incandescent Electric Lamp Socket*, F. Thone, 418,426. *Electric Arc Lamp*, J. H. Bunnell, 418,444. *Electric Light Carbon*, L. Saunderson, 418,474. *Electric Light Fixture*, G. C. Baillard, 418,636, December 31. *Electric Arc Lamp*, C. E. Scribner, 418,757. *Incandescent Lamp Holder*, I. Storey, 418,855. *Electric Arc Lamp*, E. C. Russell, 418,987, January 7.

Measurement:—*Electric Meter*, C. A. Pratt, 418,472; A. J. Frager, 418,559, December 31.

Medical and Surgical:—*Electro-Therapeutic Apparatus*, F. J. Kneuper, 417,923, December 24. *Electric Belt*, C. H. Grimley, 419,018, January 7.

Metallurgical:—*Process of Extracting Gold and Silver from their Ores*, H. F. Julian, 418,134, December 24.

Metal Working:—*Method of Making Collars on Axles by Electricity*, H. Lemp and E. Thomson, 418,198, December 31. *Method of Welding by Electricity*, C. L. Coffin, 419,032. *Method of Electric Welding*, same, 419,033, January 7.

Miscellaneous:—*Electrical Apparatus*, C. D. Baker and L. G. Bronson, 417,217. *Electric Circuit*, J. C. Wilson, 417,304 and 417,305. *Electric Stenographic Pen*, A. S. Cooper, 417,407. *Electric Fan*, P. Diehl, 417,474. *Method of Regulating the Tension of the Electric Current*, C. Dihlmann, 417,668, *Musical Instrument*, R. W. Pain, 417,690. *Lightning Arrester*, P. Winsor and A. Wurts, 417,694; P. Winsor, 417,695, December 17. *Electric Cam*, H. S. Prentiss, 417,742. *Automatic Circuit-Closer*, J. Von der Kammer, 417,758, *Device for Demagnetizing Watches*, F. J. Whiton, 417,763. *Electric Circuit Controller*, F. A. Lane, 417,926. *Magnetic Toy*, G. W. Miatt, 417,931. *Magnetic Rubber Stock Cleaner*, N. C. Mitchell, 418,041. *Electrical Toy*, H. G. Rogers, 418,069; H. G. Rogers and A. M. Coyle, 418,070. *Automatic Vending Machine*, H. G. Rogers, 418,071, December 24. *Electric Exercising Machine*, E. W. Robinson, 418,227. *Lightning Arrester*, E. Thomson, 418,249. *Machine for Beveling Stereotype and Electrotype Plates*, J. Manning, 418,292. *Type-Setting Machine*, J. B. Odell, 418,321. *Screw Cleat for Electric Wires*, G. E. Huff, 418,369. *Method of Finding the Positions of Distant Objects*, B. A. Fiske, 418,510. *Apparatus for the Manufacture of Gas*, M. C. Burt, 418,550. *Apparatus for the Manufacture of Gas by Electricity*, same, 418,551. *Process of Electroplating Dental Plates*, J. G. Ward, 418,662. *Electro-Magnetic Type-Setting Machine*, W. Dreyer, 418,664, December 31. *Lightning Arrester*, E. A. Sperry, 418,824. *Carrier System*, I. E. Storey, 418,856. *Electrical Indicating Apparatus*, G. A. Holt, 418,871. *Electric Deep Sea Sounder*, A. J. Cooper and E. E. Wigzell, 418,889. *Electro-Magnetic Transmitter*, J. T. Williams, 419,166. *Electric Pen Holder*, C. W. Reitler, re-issue, 11,058, January 7.

Railways and Appliances:—*Electrically Propelled Vehicle*, W. Main, 417,259. *Method of Operating Electric Railways*, E. E. Ries, 417,338. *Train Signal*, D. S. McElroy, 417,438, December 17. *Device for Suspending Electric Conductors*, S. H. Short, 417,747. *Device for an Electric Car-Signal*, J. P. Runkel, 417,842. *Electric Heating Apparatus for Electric Railways*, R. M. Hunter, 417,920. *Motor Truck*, E. Peckham, 417,937. *Vehicle Motor Gear*, same, 417,938. *Electric Railway Contact*, F. O. Blackwell, 417,974, December 24. *Electric Railway Signal*, E. C. Wiley, 418,258. *Electric Railway*, H. W. Libbey, 418,373. *Electric Brake Mechanism for Cars*, W. H. Darling, 418,402, December 31. *Means for the Electric Propulsion of Vehicles*, D. E. Johnson, 418,843. *Cable Railway Signal*, J. H. Pendleton, A. Bryson, Jr., and C. Tiers, 418,850. *Electrically Propelled Vehicle*, R. M. Hunter, 418,893. *Electric Heating Apparatus for Electric Railway Systems*, M. W. Dewey, 418,911. *Apparatus for Propelling Vehicles by Electricity*, F. Wynne, 419,094, January 7.

Secondary Batteries:—*Secondary Battery*, J. W. Swan, re-issue, 11,047, December 17. *Electrode for Secondary Batteries*, H. G. Osburn, 418,140, December 24. *Secondary Battery*, A. E. Woolf, 418,483, December 31; H. E. Dey, 418,700. *Cut-Out for Secondary Batteries*, same, 418,701 and 418,702. *Method of Making Secondary Battery Plates*, same, 418,703, January 7.

Telegraphs:—*Quadruplex Telegraphy*, C. L. Healy, 418,284. *Mechanical Telegraph Instrument*, J. H. Bunnell, 418,443, December 31.

Telephones and Appliances:—*Telephone Exchange Apparatus*, J. J. O'Connell, 417,271. *Multiple Telephone*, A. M. Rosebrugh and T. R. Rosebrugh, 417,511. *Telephonic Instrument*, W. C. Barney, 417,660, December 17. *Ear-Phone Rest*, G. E. Christie, 418,682, January 7.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in February, 1890.

Reported for the ELECTRICAL ENGINEER, by F. B. Brock, *Patent Attorney*, 639 *F street, Washington, D. C.*

Circuit for Chemical Telegraphs, T. A. Edison, 135,531, February 4, 1873. *Telegraph Repeater*, L. T. Lindsey, 136,251. *Duplex Telegraph Instrument*, J. B. Stearns, 136,274. *Electro-Magnetic Motor for Telegraphs*, L. T. Lindsey, 136,250.

[Drawings and specifications of any patent will be furnished by Mr. Brock at cost, 15 cents each.]

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers.*

VOL. IX. NEW YORK, MARCH, 1890. No. 99

BACKSHEESH! BACKSHEESH!

JAMES MURPHY is a rumseller whose saloon confers distinction upon the corner of Third and Monmouth streets, Jersey City, N. J. James is perhaps better known among the dwellers in that unsavory vicinage as "Cork," possibly by way of delicate compliment to the city of his nativity. Last fall, to the profound amazement of all decent people, "Cork" Murphy received the party nomination for Assemblyman in his "deestrict" and was subsequently elected to a seat in the Legislature of New Jersey. How this undesirable result was brought about may possibly be conjectured in the light of recent disclosures concerning fraudulent counting and ballot-box stuffing in certain precincts of Jersey City.

Mr. Murphy's intimate and prolonged acquaintance with the commodity known as "Jersey lightning" has apparently qualified him, in his own estimation, to arrogate to himself the regulation of the electrical industries of the state. Accordingly, we find him promptly on hand with a bill for fixing the rates for electric lighting. It is too long to quote, but two or three of its provisions will serve to show its character. The maximum rate for a 16-candle incandescent lamp is fixed at half a cent per hour, and a 10-candle lamp at one-sixth of a cent per hour, while by way of a clincher the bill further provides that if any company shall "ask or demand" any rate in excess of those fixed by the bill, all its franchises and privileges shall thereupon be forfeited, it shall be subjected to a penalty of $500, and all its fixtures "shall become obstructions and nuisances" and be subject to summary abatement by the authorities.

Imagine the glow of virtuous indignation that would overspread the ordinarily stolid and expressionless countenance of Mr. "Cork" Murphy, in case some electric light man should introduce a bill compelling him and his confreres to reduce the retail price of lager-beer from five to two cents per glass, on pain of being officially declared "obstructions and nuisances." But even at this absurdly low figure these philanthropists would receive $10 for each keg of beer disposed of, which costs less than $8, a profit of at least 25 per cent., which is, we fear, far better than the electric companies are doing. But when Mr. Rumseller Murphy charges the poor workingman, as he does, $25 at retail for such a keg of beer—a profit of over 200 per cent.,—he undeniably constitutes himself a most oppressive "obstruction;" all the more unendurable too when we consider that the victim of electric light extortion may take refuge in kerosene or gas; but what, we ask, is the poor laboring man to do, who though consumed by thirst, cannot afford to buy Murphy's beer?

Mr. Murphy's unfriendliness to the electrical industries —no less than to the Queen's English—is further shown by another bill, introduced by him at the same time, the preamble of which sets forth that:—

> *Whereas*, Life and property is in constant danger by reason of the multitude of wires now suspended from poles *and other contrivances* in the public streets in the cities of this state; and, whereas, wires *charged with electricity* are suspended in many places from the same poles on which *ordinary* wires used for telegraph purposes are strung, and by reason of such proximity do render the said wires dangerous when charged with electric current by contact with electric wires; therefore be it enacted, etc.

This bill requires that wires of every description shall be insulated, no exception being made in the case of fence-wires, stove-pipe wires, or even political wires, which latter most alarming oversight we hope Mr. Murphy will remedy at once, and thank us for calling his attention to it.

Still another of Mr. Murphy's bills orders all the telegraph and telephone wires in cities to go underground within one year.

Mr. Murphy's solicitude for the safety and welfare of the public is really touching, in view of the fact that the liquid damnation dealt out from Mr. Murphy's saloon has in all human probabilities slain more victims, made more widows and orphans, inflicted more bodily injuries, and been the direct cause of more casualties of every kind, ten times over, than all the electric plants in the state of New Jersey put together.

We shall try to keep an eye on the members who support Mr. Murphy's bills.

THE KANSAS CITY MEETING OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

WE devote the greater portion of our present number to a somewhat condensed report of the proceedings of the Annual Meeting (eleventh semi-annual) of the National Electric Light Association, held at Kansas City, February 11, 12, 13 and 14, with the greater part of the papers read and presented.

The Association still includes in its membership but a fraction of the number of owners or managers of central station electric plants in the country, but it is doing good work for the whole of them in settling down to the careful consideration and discussion of technical and administrative features of the business of electrical distribution that are vital to its prosperity, and in giving something like adequate attention to legislative questions, touching the regulation of that industry, that are cropping out in state and municipal legislatures in various directions.

It was a long journey to Kansas City from the seaboard states, where most of the members of the association are to be found—and attendance at the meeting involved the expenditure of a week's time; but it seems to be the general opinion among all who left their accustomed vocations for the convention, that the week was well spent in the work of the association; to say nothing of the many pleasures enjoyed on the way and at Kansas City through the generous hospitality of western hosts.

The report of the secretary and treasurer showed an increase of membership since July 31, 1889, and a very gratifying improvement in the financial affairs of the association. Whatever apprehension had been felt of defection on the part of associate members, after the convention of August last, are now, happily, dissipated by the figures of the secretary's report, and by the very large attendance of members of that class at Kansas City.

As in so many political gatherings nowadays, harmony was the desire of the officers and executive committee. Fortunately this was attained throughout the convention, and that without suppression of the utmost freedom in discussion or in the expression of opinion. The only menace to the general good understanding that characterized the meeting arose from the very extraordinary and ill-advised attempt of Mr. F. A. Wyman to cut off a member's right to introduce a resolution without first submitting it to the executive committee. The president and members present put Mr. Wyman out of sight as soon as they perceived the significance and absurdity of his "point of order," which thus, happily, fell short of becoming a point of *dis*order.

Among the reports of committees, nearly all of which gave evidence of more work than can generally be got out of committees during the period between semi-annual meetings, that of the Committee on Standardization of Potentials on Street Railways furnished much useful information and valuable suggestion. Through systematic enquiries addressed to all electric railway companies and to the companies manufacturing electric railway outfit, the committee had ascertained, and reported, that the potential employed varied from 220 to 800 volts. The committee found that but nine lighting companies had undertaken to supply railway companies with current. They also reported that on railways operating not less than 15 cars, only one-third of the total horse-power provided for at the central station has ever been required; that on roads running 5 to 15 cars the greatest load has not exceeded 50 per cent. of the total power, and that upon smaller roads the load varied from 50 to 80 per cent. of the station power. These figures are not less interesting to lighting companies having opportunity to supply current for power than to street railway companies. The committee very judiciously advised lighting companies against attempting to furnish power current from their existing lighting machinery, advocating rather the installation of special power plant where opportunity for power service exists. Their recommendation in this regard was enforced by considerations fully set forth in the report, which is printed in full in other columns.

The insurance committee's report led to a long discussion and developed very freely the prevalent opinions in the association on that topic.

The facts of the insurance problem are about as follows: Although, as our readers are aware, some competent underwriters, particularly in New England, take electric risks at reduced rates, regarding electricity as the safest of illuminants, yet many electric lighting companies throughout the country are unable to place their risks except at uncommonly high rates, often prohibitive. It must be that the New England underwriters are wrong (disproved by the fewness of their electrical losses), or that the uninsurable risks are really too hazardous; or that insurance companies generally are unable, through their inspection service, to determine whether they are or are not desirable risks. The truth lies in both the latter propositions; that is, both are partially true. The soundly built, equipped and managed stations are good risks; the flimsy, ill equipped and slovenly managed stations, of which there are still too many, offer no just ground of complaint against underwriters. What to do? The insurance committee recommended that electric lighting companies appoint an instructor to teach insurance inspectors how to distinguish between good and bad electrical risks. This proposition, the committee confessed, had met with a frigid reception at the hands of underwriters' boards to whom it had been communicated. A more important recommendation of the report was that advising the formation of a mutual insurance association, for the insurance of central stations. The merits of such a plan are very obvious. Such an association, consisting mainly or largely of central station owners would be able at once to exercise the most competent and thorough expert inspection of risks, and might easily and soon accomplish more than any other agency could do toward reforming defective construction, equipment and management of central stations wherever needed. It is to be hoped that the adoption of the committee's report will be speedily followed by the organization of an insurance association similar to that proposed, and of which a prospectus was filed with the report. Mr. Marsden J. Perry, unanimously chosen president of the association at the election on Friday, warmly supported the mutual insurance project, and, from his known energetic action in backing his opinions, he may be expected to give that measure prompt and effective attention.

A very gratifying incident of the insurance discussion is to be noted in the good set terms in which Captain Brophy—than whom no one in Boston or elsewhere is more competent to speak touching electricity and fire risks—characterized the finding of the Fire Marshal of Boston, which attributed the Thanksgiving Day fire in that city to electric wires. Said Captain Brophy: "Any one who knows anything about the condition of affairs there, must know that that was not the cause of the fire. I certainly do; and if I had any respect for the electrical knowledge of the worthy Fire Marshal previous to his report, I have since lost it."

Among the many important topics dealt with by the convention was that of "paralleling;"—the establishment of competing plants alongside of those already established, too often encouraged or even incited by rival manufacturing companies, and invariably leading to ruinous competition and the discredit of the business of electric lighting as an investment. A strong committee On Relations Between Parent and Sub-Companies, with Mr. Perry at the head, was appointed to take the matter in hand.

The work of the Committee on Legislation in promoting the organization of State Electric Light Associations had resulted in the formation of ten such bodies. How effectual such state organizations may be made in protecting the business of its members from hostile legislation may be inferred from the success, a few weeks ago, of six or eight lighting companies in various towns of Virginia, who, without organization, sent representatives to Richmond and defeated the pending bill to restrict voltages.

THE common observation that the recital of one fact carries more weight than a dozen theories, has received a curious confirmation in the results which have followed the publication of Mr. Edison's widely circulated article in the *North American Review* on the dangers of electric lighting. The article was a plea against the admission into use, under any conditions, of high tension and alternating electric currents; a proposition which was supported, by a really formidable array of more or less pertinent theoretical objections. But in citing one fact, viz: the fusion of a cubic yard or so of iron, copper, and even street paving-stones into a solid mass, by the electric heat arising from an accidental cross in the conductors of a low tension central station plant, Mr. Edison unwittingly indicated the one radically weak point—from a technical point of view—of the low tension, direct-current system of distribution, the merits of which he sought to advocate, and that is the interconnection of all the mains, by which means the aggregate generating power of the central station may be instantly concentrated upon a defective point wherever situated with the possibility of the most disastrous results.

The views set forth by Mr. Edison, and especially the accident recorded by him—which we think had hitherto escaped publication—has led to a somewhat exhaustive discussion, in the public journals and elsewhere, of the whole subject of safe electrical distribution, the general drift of which would appear to justify the prediction that the alternating system, which, by its complete electrical separation between the house and street wiring, furnishes protection to the consumer from fire as well as from shock, will hold its own for long-distance distribution, however large a field may remain to low tension direct distribution over relatively restricted areas. No system can claim absolute immunity from danger. Energy enough to burn or kill must be employed in any method of electrical distribution for light or power, just as it must be employed in every steam engine; but it can be confined to its proper work, and the danger can be reduced to almost nothing by sound knowledge and practice in both cases.

THE future of the subway question in New York, now depends largely upon the result of the injunction suit brought by the Manhattan Electric Light Co. and Geo. E. Armstrong against the Mayor, the Board of Electrical Control and the Consolidated Telegraph and Electrical Subway Co., to restrain the Mayor and the Board from authorizing the Consolidated company to transfer to the new Standard Electrical Subway Co., or any other, any or all of its subways and the right and obligation to build subways for electric light and power conductors, and to enjoin the Consolidated company from making such a transfer of its rights and duties. Both motions were heard together.

Argument was begun before Judge Andrews in Supreme Court Chambers March 6, and was continued next day. Besides the attorneys of the Manhattan company, other counsel, representing several other electric light companies interested in presenting the proposed transfer appeared, and it is evident that the struggle to forestall the ownership of a general electric light and power subway system by the Standard company will be a determined one. The Westinghouse companies controlling the Standard Electrical Subway Co. evidently have comprehensive plans on foot for electrical distribution in this city.

Meantime the Edison companies, constructing and owning their underground systems, have the good fortune to be out of the fight, which apparently does not touch or menace their operations. They may, therefore, be presumed to behold with serenity the conflicts between other and rival interests.

THE recent destruction of the magnificent building of the University at Toronto, one of the very finest specimens of architecture on this side of the Atlantic, is a loss which the cause of science as well as of Canadian education can but ill afford. It seems that the fire was caused by the breakage of a tray of kerosene lamps, but we are entirely at a loss to understand why it has not been attributed to electricity. The successful demonstration of such a proposition should present but little difficulty to the experts of the daily press, who only the other day, informed an open-mouthed public that an incipient fire in one of our large hotels, which was extinguished with some difficulty, was due to the wires of an electric call-bell which had been installed a day or two before, and which were attached to that most incendiary of all sources of electricity—a cell of Leclanché battery.

SELDOM, if ever, has the Electric Club of New York been better entertained and instructed than it was Thursday evening, February 20th, in listening to the address of Mr. Grosvenor P. Lowrey on "Patent Law, and What Constitutes an Invention." In his inimitable manner Mr. Lowrey traced the history of patent systems from their source, and descanted with his peculiar humor upon perplexing features of the administration of the United States patent laws, illustrating from noted cases. As to what constitutes an invention, he felt compelled to say, as doubtless would also every other thoroughly experienced patent lawyer, that he did not know.

THE following item reaches us too late for insertion in our news columns:—

> P. F. Kobbe, of New York, formerly treasurer of the United States Electric Lighting Co., has been elected to fill the same position with the Westinghouse company, vice Caldwell, resigned. The vacancy in the assistant treasuryship of the same company caused by the resignation of A. T. Rowand, has been filled by the election of W. L. McCullagh. Mr. Rowand remains, as before, secretary of the company.

MUCH to our regret, we are compelled to defer till April, the publication of the third and concluding portion of Mr. Wm. L. Puffer's important article on "Data and Plots of Various Incandescent Lamps, With an Improved Method of Testing."

ARTICLES.

THE PRACTICAL WORKING OF THE ELECTRICAL SUBWAYS OF NEW YORK CITY.[1]

BY WILLIAM MAVER, JR.

KNOWING very well the wide-spread interest that has attended the placing of wires underground in New York city, I have been glad of the opportunity to gather and prepare for presentation to you this evening, such data and information relating to that subject as I have thought would be, and as I hope may be, found of the most value.

I observe that our worthy secretary has announced me in the notice of the meeting as the electrician of the Consolidated Telegraph and Electrical Subway Co., and quite correctly so. I desire to say, however, perhaps unnecessarily, that I have prepared this paper in my unofficial capacity, and am, of course, alone responsible for what may be contained therein.

The customary reply to an inquiry as to what is the best arrangement for an electrical subway is, "Build a tunnel under the streets and place the wires on the walls within easy access of workmen, and into such a tunnel put also the gas and water mains, etc."

Assuming that this would be a satisfactory solution of the underground question, if it could be arranged, let us consider what the cost of such an arrangement would be.

It has been estimated that a subway suitable to contain all the electric wires, gas and water mains of New York city would cost $430,000 per mile. This for Broadway alone from Bowling Green to Central Park would mean an outlay of about $2,150,000, and if such a tunnel were to be built throughout the entire route of the now existing electrical subways of New York city, the bill would foot up to nearly $30,000,000.

This amount it will, I think, be generally admitted, is virtually prohibitory of any such subway at present, and if that is the case, the fact will perhaps make those who have had preconceived ideas in favor of a universal tunnel scheme more tolerant of the electrical subways we have, the practical working of which I am to endeavor to describe this evening.

When the first whisperings of a desire on the part of the public or press to have electric wires in the large cities go underground, were heard in this country, it will be remembered the telephone people with one accord admitted that it would be quite feasible for the telegraph and electric light people to operate their wires underground, but claimed that for them to attempt to operate their circuits thus, meant irretrievable ruin. Equally convinced also were the telegraph people that while it would be very easy for the electric light companies to work their circuits underground, it was quite out of the question that telegraph wires could be operated successfully in subways, since the increased electrostatic and electro-magnetic effects would completely destroy quadruplex and fast automatic telegraphy. And no less emphatic was the opinion of the high tension electric light people that the telegraph, the telephone and the low tension electric light systems could, if required, all go underground without detriment, but it was utterly impossible for them to do so, and at the same time to operate their circuits successfully.

New York city was no exception when the time came to place the wires underground. Gradually, however, the telephone yielded—more gradually the telegraph, but more tenaciously the majority of the high tension people clung to their statements, and the experiences of the cities of Chicago, Philadelphia—especially Philadelphia—and elsewhere were cited as evidence of the futility of any attempt to operate high tension currents underground. These experiences were held to show that no insulation could be procured which would withstand the pressure of the high electromotive force employed on high tension circuits. In addition to this it was also asserted that the requirements of the Subway company regarding the insulation resistance of the underground conductors was high beyond all precedent and unobtainable in practice, and that even if such insulation could be obtained it would be impracticable to make tests of the conductors showing them to possess the insulation resistance required by the rules.

It is very far from my intention to go into a history of the opposition offered by the different electrical companies to placing their wires underground, and in so far as I have just alluded to it I have done so for the purpose of quoting in a general way some of the reasons given by the companies for this opposition, and this only that we may see how far the surmises of those who were thus averse to placing wires underground have been verified by actual results.

It is told of a certain noted geologist that when a specimen of gold quartz, which had been found in a locality where he had stated no gold would ever be found, was shown him, he remarked that if it really had been found there, nevertheless it had no right to be there.

I can imagine that there are many persons—perhaps not in this room—but somewhere, who, if told that telephone, telegraph, high and low tension electric light circuits, and even "deadly" alternating circuits, are to-night in this city working successfully underground in the same streets and on the same side of the streets would reply, "If they really are working successfully there they have no right to be."

In preparing this paper I have found that the subject has almost naturally arranged itself under the following general headings, namely:—

1 The type of conduits used in the subways.
2 The drawing in of cables.
The methods of distribution.
3 The cables employed in the subways.
4 Present condition and probable duration of cables.
6 Joints.
7 Lead covered cables.
8 Insulation and tests.
9 Alleged dangers of the subways.
10 Gas in the subways.
11 General remarks.

I have been unable to obtain with any degree of accuracy the extent of electrical subways or the amount of wire placed in them in the cities of Europe, and, therefore, I cannot say definitely how New York to-day compares with such cities as London, Paris and Berlin, in that respect. But I incline to the belief that it may be found that New York will fall but little, if at all, behind those cities. In New York city to-day there are 73 miles of electrical subways and 1,017 miles of ducts. In these ducts there are 10,906 miles of telephone wire, 945 miles of telegraph wire (including fire alarm telegraph wires), and 457 miles of electric light wires. These subways have a capacity for about 45,000 miles of telephone and telegraph wires and 2,000 miles of electric light wires.

CONDUITS.

There are in the New York electrical subways eight different conduit systems, namely: the Dorsett, the Wyckoff, zinc tubing in hydraulic cement, sheet iron cement lined pipe, wrought iron pipe in hydraulic cement, wrought iron pipe in asphaltic concrete, the Edison iron tube and the Johnstone sectional cast iron conduits. All of these conduits have been frequently described; I shall, therefore, just briefly refer to each.

The Dorsett system consists of blocks formed of a material the ingredients of which are pitch, coal tar and fine gravel. The blocks are moulded, with tubular openings about 2½ inches in diameter, from end to end. The blocks are about four feet long and one foot cross-section. The blocks are placed end to end in the trench, and are joined together by pouring between the ends a liquid compound of pitch and tar which speedily hardens. This compound is prevented from entering the ducts by sleeves which are placed in each duct between the junction of every two blocks. There is about one mile of this conduit, containing 16 miles of ducts, on Sixth avenue. It is used for telephone and telegraph conductors. This conduit was laid three years ago. So far as I can learn it is in a fair state of preservation to-day, but not perfect, the blocks having, in some instances sunk and thus put the ducts out of alignment. It may be noted here that ½ inch tarred hemp, guide ropes of which were laid in these ducts when this system was constructed, to be in readiness when cables were to be drawn in, show plainly in numerous places, signs of deterioration, said to be the result of dryrot combined with the gases found in the ducts.

---

[1] A paper read before the Forty-third Meeting of the American Institute of Electrical Engineers, New York, Feb. 18, 1890.

The zinc tube conduits are laid in Fifty-eighth street. The zinc tubing was intended to serve simply as a mould around which hydraulic cement concrete was to be placed, with the expectation that when the zinc had corroded, the tube formed by the solid cement would remain intact. About one mile of this conduit has been in successful operation for three years, but the difficulty attending *the construction* of a conduit formed in this way was so great, owing to the frailty of the zinc tube, which readily gave way under moderate pressure, that its use has not been further extended.

The sheet iron cement lined pipe conduits are made in single or multiple tubes of two, four, six or more ducts, as may be required and in lengths of eight feet. The tubes are connected together by a ball and socket joint. These conduits are made as follows: a sheet iron tube eight feet in length is held vertically; inside of the tube is placed a smaller brass tube; semi-liquid cement is poured into the annular space between the brass and sheet iron tubes. When the cement has solidified the brass tube is withdrawn. The cement tube is then ready for the subways. There are about 113 miles of ducts of this conduit in the subways, and during the coming summer it is expected many times this amount will be laid in New York city.

There are about 15 miles of creosoted wood ducts in the subways, known as the Wyckoff conduits. These ducts are formed of wood piping similar to ordinary pump logs. There are lead covered telephone cables in these ducts, and the action of the creosote upon the lead covering is being carefully watched. These ducts have been in operation for three years. I am informed that detrimental effects are noticeable in the lead covering of the cables, which is alloyed with three per cent. of tin.

The bulk of the subway conduits consists of wrought iron pipe laid in hydraulic cement concrete. These pipes are 20 feet in length and vary in diameter from two to three inches. The thickness of the iron is .217 inches.

In laying all of these pipe conduits the bottom of the trench is first leveled to grade; planks are then set against the side of the trench to sustain it. A layer of concrete is then laid and rammed in the bottom of the trench. On this is placed a row of iron pipe, next a layer of concrete, then another row of pipe, and so on, until the desired number of layers is attained. The number of pipes in a row depends upon the topography of the street and the location of existing gas and water pipes, which it is desired to avoid; and the number of rows upon the total number of pipes desired to be laid in a given subway. In order to add strength to the mass and to protect the ducts from mechanical injury, the concrete is applied more thickly on the bottom, top and sides of the subway than between the pipes. There is placed over all a two inch yellow pine planking, heavily creosoted, to further protect the conduits against injury, from picks, crowbars, etc., in the event of future excavations in the streets.

The wrought iron pipes are joined end to end by a coupling screw joint with a tapering or vanishing thread. By the use of this form of thread, I am informed, the rate of laying this piping is increased 50 per cent. These tubes are delivered free from burrs, and have a smooth inner surface. The pipes are sometimes asphalted to prevent rusting, but should they in course of time rust, it is expected, as in the case of the zinc tube, that the concrete will preserve the shape of the duct intact. There are close upon 550 miles of wrought iron piping in the subways.

The facility with which a pipe conduit conforms to the varying condition of the crowded streets of large cities, as found in the process of trenching, is one of its chief advantages.

The main reasons which have led to the extensive use of wrought iron piping in the subways are its great strength, its adaptability to varying conditions of the street and the rapidity with which it can be laid.

The Edison system consists of wrought-iron pipe in which are placed the copper conductors or rods. These conductors are wound with rope and the pipe is filled with an insulating compound of trinidad asphaltum, rosin, paraffine and linseed oil. These iron pipes are laid directly in the earth. There are about 50 miles of this pipe now laid in New York city.

The subways are in many cases on both sides of a street, and as a rule the telegraph and telephone wires are assigned to ducts on one side of the street and the electric light wires to ducts on the opposite side; but in numerous instances the electric light wires are operated in distributing ducts on the same side of the street as the telegraph and telephone wires, and without detriment to the latter.

MAN-HOLES.

Access is had to the conduits of the New York subways by means of man-holes, placed at an average distance of about one-twenty-fifth of a mile apart. The man-holes are, with a few exceptions, built of brick laid up in concrete cement, with hydraulic concrete bottom. The outside of the walls is coated with cement to prevent moisture and gas from penetrating.

Access to the man-holes from the street is had through the cast-iron head which is set on the brick work, and which is provided with double covers. The upper or street cover weighs about 350 pounds; the lower cover is provided with a rubber gasket to prevent ingress of street water into the man-hole. This cover is funnel-shaped in order that any water which may enter through the upper cover may be drained away from the gasket. The lower cover is screwed down upon the gasket by a gun metal bolt and cross-bar. The upper cover is loose upon its bearings. The ducts enter the man-holes at a point easily accessible to the workmen while standing on the bottom of the man-hole. The average width of the man-holes is about five feet, and varies from 5 to 10 feet in depth. The hand blower used for driving out gas from the man-holes is shown, also the iron frame work or cage which is placed around the opening to the man-holes when the cover is removed.

The foregoing mentioned conduits may be considered as belonging to the regular subway system of New York city.

There are, however, several other conduits in operation in this city, namely, the Brooks, the Western Union and about five miles of telephone cable laid in wooden boxes filled with sand. The Brooks' system has been so repeatedly described I need not further allude to it. The Western Union subway consists of an iron pipe about six inches in diameter, into which wires have been drawn.

RODDING.

The electrical subways of New York city, with the exception of the Edison system, are of the class known as the drawing in and out systems. The first process in drawing a cable through a duct which is not easily accessible except at its ends in the man-holes, is obviously to provide a means of drawing in the cable. This is done by a process technically termed rodding, which consists of pushing rods through the duct from one man-hole to the next. A rope is then attached to the end of the rod and the rod is withdrawn bringing the rope with it. This rope is then employed to haul in the cable. As some of the man-holes are over 500 feet apart, and it would not be convenient to procure a continuous wooden rod of that length—rods of about four feet in length furnished at one end with a screw and at the other end with a screw socket are used. These are placed in a bunch in the man-hole and are attached by the screws, one to the other, as many as are required to reach to the distant end of the duct. The rods are then detached as they are drawn out by unscrewing the ends. This is a specimen of this form of rod (showing). It is the one most generally used. There are other forms of rod also in use in the subways. This (showing) is one of them. It is furnished with a slot into which the T-end fits, but into or out of which it can only go at a certain limited angle. Therefore, while this joint or connection is quite loose there is no likelihood of the rods coming apart in the duct, because the diameter of the ducts does not permit a sufficient movement of the rod at the joints. The time taken in rodding a duct of 300 feet in length is about 20 minutes.

Continuous steel wire rods about one-quarter of an inch thick and from 300 to 500 feet long are also used for rodding the ducts. These rods are mounted on a reel about six feet in diameter which is placed adjacent to a manhole and from which it is reeled off as the rod is pushed through the duct. When this operates freely, it is more expeditious than the wooden rod methods just described, as the time taken in jointing up the rods is saved; but it is found that the wire occasionally buckles in the duct and, furthermore, it is more apt to be caught by any obstruction or unevenness, than are the wooden rods, so that by many the latter are employed as being the more expeditious, all things considered.

There is also another method of rodding sometimes employed, which consists of a long spiral steel rod, the spiral of which is about one inch in diameter. On the circumference of the spiral small wheels are mounted to ease the friction. This rod is also placed on a reel and wound off as it is fed into the duct. This spiral while quite elastic is yet capable of withstanding considerable pressure. This rod is pushed into the duct in the usual way. The expense and the weight of this form of "rod" is somewhat against it, although I am informed that by its use a duct can be rodded in one-half the time required by the screw rods.

Before those employed in the work of drawing in conductors into subways had devised and settled down to the forms of rods just described, many bright minds were at work on the question of how to rod the ducts. The scheme of tying a string to a rat's tail and sending him through the duct with a ferret after him was tested practically in Brooklyn, I believe, but the plan was not generally adopted. In the case cited, it is stated that the ferret overtook the rat and stopping to eat him was overcome by the gas and asphyxiated. This necessitated the tearing up of the street to get at the remains.

In Chicago, it was seriously suggested that a wooden ball with a string attached to it, be placed in the duct and that then a hose connected with a neighboring hydrant be inserted in the duct. The water was to force the ball through the duct. This plan was found to work successfully so far as getting the ball through was concerned, but it flooded the man-holes, and was not put into general use, even in Chicago.

Another inventor devised what he called a mechanical creeper, which was designed to advance itself through the ducts by putting out arms against the walls and thus pushing itself along.

Sometimes in rodding, obstructions are met with, caused by pieces of cement, stone, dirt, etc., gaining access to the ducts. Sometimes, also, obstructions are caused by uneven joints in the conduits. Ordinary obstructions are removed by a mandril placed on the first rod.

DRAWING IN CABLES.

After the rope has been attached to the cable, the latter is then "threaded" through the duct. The attaching of the rope to a cable is a matter of some skill. The connection is so made that the strain comes chiefly on the conductors. To prevent the cable or cables from twisting as drawn in, a swivel is inserted in the rope near the cable.

The manner of applying the force necessary to pull the cable through the duct depends upon the size and length of the cable. If it is a small cable, say 300 feet in length, it can be drawn in by two or three men. If it is a large cable, or if four or six small cables are to be drawn into one duct, as is frequently done, more elaborate drawing in apparatus is used. This generally consists of some form of winch. The largest telephone cables are drawn in by a winch of special construction, in which the power is transmitted through the intervention of wheel gearing. As a rule, it may be said that in the matter of drawing cables into the ducts the work has been satisfactorily performed. In a few instances mistakes have been made, as in the attempt to draw too many cables into one duct—the old problem of putting a three inch bung into a two inch hole—and in the attempt several lengths of cable have been jammed in the ducts and injured.

As many as six electric light cables, No. 4 B. & S. conductors have been repeatedly drawn at once into a three inch duct. It is not deemed advisable to draw cables into or out of ducts over cables already laid, but in cases of necessity it has been done without injury to the cables.

As the weight of a No. 4 B. & S. lead covered cable is for 300 feet, say 250 pounds, an idea may be obtained of the force required to draw in six such cables. I am informed that cables weighing in the aggregate 5,510 pounds, have been drawn at one time into one duct.

METHODS OF DISTRIBUTION.

It is, of course, a comparatively easy problem to arrange an electrical subway for trunk line circuits. The difficulty arises when the question of distribution of the current from the main conduits is to be considered, as when, in the case of the telegraph and telephone service, it is desired to furnish city customers with circuits; and in the case of electric light service when it is required to make house to house or street lamp connections.

In the case of telegraph and telephone distribution, subsidiary pipes or ducts are generally led from an adjacent man-hole to the front or side of buildings, whence the cables are continued to the roof of the building or to the back yards, from which latter points the circuits are radiated as required.

The cable of the telephone company is generally made up into 50 pairs. When this number of circuits is not required in one block or series of blocks, the cable is forked in the man-hole, one portion of the conductors being led in a smaller cable in one direction, another portion elsewhere as may be required. This method of distribution has been found convenient and satisfactory.

Distribution of the electric light current is effected in several different ways in the New York subways. For street arc lamps the circuit is usually looped from the manhole to the lamp post through a subsidiary iron pipe.

For easy access to houses and to lamps in the middle of blocks, distributing ducts are laid above the trunk ducts as near the surface of the street as practicable. The average distance from the surface of the street being, perhaps, 18 inches.

The Johnstone sectional conduit, has hitherto been the most extensively employed for this purpose in New York city. This conduit consists of sections of cast-iron ducts about five feet in length. The sections are placed directly above each other and are held together when in position by removable clamp pins. The upper section rests in a groove in the lower section. Each section of the conduit is divided into 2–6 or more compartments or ducts—depending upon the size of the section,—the ducts being formed by removable partitions or slats held in position by suitable channels or grooves within the sections. Opposite each house or every alternate house, a hand-hole is provided in the upper section of the conduit. This hand-hole consists of a removable cover, about two feet in length, on the upper section, and the side of the section at this point is provided with a branch or spigot.

This conduit is laid directly in the earth, not in cement. When it is desired to obtain access to a conductor to tap or loop a circuit into a building, the paving and earth are removed from the street and the cover of the hand-hole is lifted, thus exposing the conductors in the ducts. A 3-inch iron pipe is run from the branch at the hand-hole to the basement or vault of the house or to the lamp post with which connection is desired to be made. This iron pipe fits the spigot at the side of the conduit. The connection is then made with the conductors by splicing on short lengths of cable leading through the iron pipe to the house or lamp. Should the conductor which it is desired to tap be at the side of the section remote from the spigot, the intermediate partitions are removed to permit the passage cross-wise of the connecting cable. After the joints are made, the cover of the hand-hole is replaced and the earth and paving are restored to their normal condition.

When a hand-hole has not been provided originally at a point where access is desired to a conductor in the conduit, the entire upper section is removed and replaced by a half section containing a hand-hole cover and spigot. This work can be done in a short time. The sections in use for this purpose are in some instances somewhat small for ease in joint making especially, as but very little slack is available when T joints are to be made, and, therefor in future, larger hand-holes will be provided. These conduits are presumably made air and water tight at the junction of the two sections, and at the ends of the ducts, by the use of plumber's putty. In view of the number of supposed opportunities for the entrance of moisture at these junctions it would be naturally expected that this type of conduit would be in a chronic moist condition. Indeed it has been predicted of it that the ducts would act as canals for the surface water, but, as a matter of fact, these ducts are almost invariably dry. There are two theories given to explain this fact. The first, that in reality the plumber's putty makes an air and water tight joint. The second, that if the joints are so imperfect as to admit water, they are quite capable of permitting its escape also. It must be said that this conduit has been found of much utility in the practical distribution of electric light current in this city.

More recently a method of distribution in which wrough iron pipes are used has been employed. This consists of a row of three or four iron pipes laid, like the Johnstone conduit, as near the surface as possible, in the earth, without concrete. Opposite every party wall, or, in other words, at distances of about 50 feet apart, iron boxes, about 18 inches square are placed. These boxes have removable covers. The ducts enter at the ends of the box but do not pass through it. The boxes are provided with sides opening also for the entrance of the subsidiary iron pipes. Access is had to these boxes also by the removal of the street paving and earth.

This method of distribution has, like the one just described, been found satisfactory. Certain mechanical improvements in the construction of both are, however, desirable, and are contemplated.

When it is desired to cross a street to reach customers subsidiary ducts are constructed.

It is frequently remarked (presumably derogatory of the existing electrical subways) that no system of house to house distribution can be considered perfect which requires the tearing up of any portion of the street to obtain access to the mains. This will be granted by any one. The same is equally true of the house to house distribution of gas and water from the street mains. In all of these cases if the connections were made from the street mains to every house and vacant lot along their routes when the mains are first laid the necessity for reopening the streets to make house connections would be avoided. But I have yet to learn that this is done by either the gas or water companies, nor have I heard that their neglect to do so has been seriously animadverted upon.

It would, therefore, seem unreasonable that the additional expense of making these connections, which may never be required, should be urged upon the users of the subways by any who have the interests of electrical industries at heart, especially while they ignore the failure of the gas and water companies to make corresponding connections.

THE CABLES AND INSULATION USED IN THE SUBWAYS.

In the telephone service in this city the cables used are chiefly of the type known as the Patterson. This cable is constructed as follows: Ordinary cotton covering is first placed around the wires. After the wires are cabled a lead covering is placed over them and paraffine is then forced into the interstices between the conductors and lead covering.

This cable has an electrostatic capacity of about .16 microfarad. The insulation resistance of the cable, laid and jointed in the subways averages about 100 megohms. The longest stretch of cable used by the telephone company in the subways is seven miles. The greatest number of conductors in any one cable is 100 or 50 pairs.

The telephone service in the underground conduits was impaired somewhat, so long as ground circuits were used, but since the adoption of metallic circuits the service is satisfactory. On the long-distance telephone circuits the seven miles of cable is, of course, somewhat detrimental.

The telegraph companies have thus far used, chiefly for underground service, kerite, okonite, Standard Underground and Patterson cables. The kerite and okonite insulation, it is well known, are homogeneous compounds. These cables are not lead covered. Of course they could be. The Standard and Patterson are fibrous cables and are lead covered.

Except in the vicinity of the underground steam pipes, the unprotected homogeneous cables have given uniform satisfaction. But, as might be expected, the effect of escaping steam upon them has been detrimental.

Fortunately the heated area in the vicinity of the electrical subways is limited to a portion of the down-town districts. Investigation has shown that the heat only reaches a harmful temperature in the neighborhood of actual leaks in the steam pipes. Measurements of the temperature of a man-hole in the worst section of the heated district have shown as high as 150° to 200° F. Since the starting of the blowers in this district to ventilate the subways a noticeable decrease in the temperature is observable, and, inasmuch as the steam heating company is achieving some success in its efforts to close up all leaks in the pipes, it is anticipated that the heat difficulty will be eventually removed from the subways.

The users of the Standard and Patterson cables state that those cables are giving very fair service in the heated portions of the subways, although the high temperature, of course, lowers the insulation resistance of the cables.

The average number of conductors in the telegraph underground cables is about 50. The size of the wire used is, as a rule, No. 16, B. W. G., and the outside diameter of a conductor, including the insulation, is 6-30 seconds. The insulation resistance of the okonite insulation is about 2,500 megohms; that of kerite 500 to 800 megohms, and that of the Standard and Patterson about 1,500 megohms per mile for the thickness of insulation just mentioned.

Outside of the injury to the cables due to the presence of the steam heating pipes, no undue deterioration of the telegraph cables in the subways has been noted.

The effect of the increased electrostatic capacity of the underground circuits has not caused any marked inconvenience in the operation of the telegraph circuits.

The comparatively low mileage of telegraph wire in the subways is partly explained by the fact that the bulk of the telegraph circuits in New York city are suspended from the elevated railroad structures. The Fire Alarm Telegraph cables in the subways do not differ very materially from those used by other telegraph companies. The fire department thus far has used Standard Underground cables.

ELECTRIC LIGHT CABLES IN SUBWAYS.

In the electric light service in the subways—and I am aware that it is around this that the greatest interest centres—there are, exclusive of the Edison system, four different types of insulation used, namely, the Bishop rubber compound, the Standard Underground, the Safety insulated and the Cobb vulcanite-paraffine cable. All of these cables are lead covered as a precaution against mechanical injury, action of acids, etc., or moisture. Specimens of these cables are on the table.

The sizes of conductors used in the electric light service vary with every company and with the character of the service. For feeders the conductors range in size from No. 6 noughts B. & S. to No. 2 B. & S. For mains, from No. 2 to No. 6 B. & S. In many instances No. 10 B. & S. is used for connecting from the mains to lamps through the subsidiary ducts.

THE STANDARD UNDERGROUND CABLE.

The insulation of the Standard Underground cable is obtained by first wrapping thick cotton thread or cord around the wire to any desired thickness. The wire thus covered is then placed in a cauldron of boiling insulating compound—a product of petroleum. This treatment displaces any moisture that may be in the cotton thread. After the cotton has been thoroughly saturated with the compound the whole is then lead covered. Care, is of course, taken by soldering up the ends of the cable to prevent absorption of moisture in shipment and in drawing into the ducts.

There are now in actual service for electric lighting purposes in the New York subways over 95 miles of this cable, carrying currents of an E. M. F. of from 300 to 3,000 volts, including many 1,000 volt alternating currents, and an additional 50 miles of the same cable will shortly be in operation. The thickness of insulation used in these cables is 5-32, 6-32 and 7-32 of an inch. This refers to the thickness of the insulation from any given point of the circumference of the conductor.

THE "SAFETY" CABLE.

The insulating material of the "safety" cable is an India-rubber compound. It differs somewhat, I believe, from the ordinary run of India-rubber compound cables in that the compound is placed over the wire, without seams or laps of any kind. This compound is vulcanized to a moderate degree of hardness sufficient to prevent decentering of the heavy conductors which it insulates, but yet it retains a high degree of flexibility.

The thickness of insulation used in No. 4, B & S. wire, 204 inch diameter, is .108 inch. The weight of this conductor, lead covered, is 4,861 lbs. per mile. Of this the wire weighs 665 lbs., the insulation 669 lbs., the tape 95 lbs., the lead covering 3,432 lbs.

A special thickness of this insulation was made in one instance in response to a call for cable to withstand a strain of 7,000 volts for arc lighting. A sample of this cable is on the table; the thickness of the insulation is .238 inches. The conductor is No. 4 B. & S. gauge. This cable is now in the subways. Its length is about three miles. I am not aware that it has yet been called upon to withstand the prescribed 7,000 volts.

There are now over 65 miles of the "safety" cable in actual use in the subways, assigned to electric light circuits carrying continuous and alternating currents of from 1,000 to 2,500 volts E. M. F., and about 15 miles additional are now being placed in subways.

THE BISHOP RUBBER COMPOUND CABLE.

The Bishop rubber compound cable is of the well-known Silvertown type; having first a coat of rubber without sulphur, then a coat of rubber compound with sulphur and over this a lapping of rubber cable which is then taped. There are two sizes of this cable in the subways, namely, No. 4 B. & S. and No. 6 B. & S. The thickness of the insulation is 4-32 inch; the thickness of the lead covering is 5-64 of an inch; the outside diameter of the cable is .65 of an inch; and the weight of the cable is about 3,432 lbs. per mile. There are of this cable in successful operation about ten miles assigned to alternating currents of 1,000 volts, and five miles to arc circuits of 2,500 to 3,000 volts E. M. F. Double this amount of this cable will soon be laid for similar purposes.

THE "COBB" CABLE.

The Cobb vulcanite-paraffine cable is of a somewhat unique construction and design. It also differs, materially in one respect, from the other cables described, in that the conductor is freely movable within its insulating medium. The cable is made in practically the following manner: A vulcanite tube is first made in lengths of about 300 feet. This tube is moderately flexible. The tubing is vulcanized in boiling paraffine. The wire is then threaded through the tube after which the sections of tubing are jointed together. A thick cord is then wound spirally around the vulcanite tube. The whole is then lead covered, and the space between the vulcanite and lead formed by the spirally wound cord is filled with paraffine.

There are about 25 miles of this cable in the subways.

In the case of the Bishop, Safety, Cobb and Patterson cables, the lead is alloyed with about 3 per cent. of tin. The lead covering of the Standard Underground cable is unalloyed, but it is covered with a thick cotton braiding soaked in "P. & B." paint (the latter a product of petroleum) which it is claimed will protect the lead from acid gases, etc., and the braid also acts to protect the lead from mechanical injury.

CONDITION OF THE CABLES.

I may say that all of these cables are guaranteed by the manufacturers for three years. This term, however, is not to be taken as signifying the limit placed upon the life of the cables by the manufacturers.

It is over a year since current was turned on the first high tension electric light circuit in the New York subways. This was a circuit in 125th street, belonging to the Harlem Electric Light Co. The insulation resistance of the cable, as measured just before the turning on of the current, showed it to be 1,750 megohms per mile. A test made of the same circuit last week, after one year's continuous service, showed it to have an insulation resistance of 1,516 megohms per mile. Since the installation of the circuit just referred to, electric light cables of the various types described, have been drawn into the subways almost as rapidly as they could be manufactured, and tests made of the conductors, months after the initial test, have shown them to be in the same electrical condition as when first laid.

There have been several burn-outs in cables in the subways within the year, but with the exception of an abandoned cable, to which I shall refer later, these burn-outs have been traceable in every case to defective joints or to mechanical injury. In all, according to there cords, and best obtainable information, there have been, exclusive of those in the abandoned cables, but five burn-outs, in over 185 miles of electric light wire during a period of active service of the conductors, ranging from one month to thirteen months.

In the case of 27 out of 34 of the electric light circuits in the subways, not a single defect of any kind has occurred since they were placed in the ducts.

There have been several instances when faults not amounting to burn-outs have been discovered by the regular tests, which have brought the insulation resistance of certain conductors below the requirements of the rules of the subway, but these defects have generally been located and removed without serious delay to the circuits. Where this has not been the case, it can be fairly attributed to the employment of untried insulation, unfamiliarity with underground service, or to the inexperience of the men to whom the work of connecting up circuits, etc., has been intrusted. For example, in a number of cases grounds have been traced to contact of the conductor with the lead covering, and the linemen so connecting them have explained that they were not aware the lead covering would cause a ground.

On several occasions grounds have been caused by the driving of nails through the lead covering of the cables or leading in wires, under the moulding inside of buildings, and again a ground was caused by a laborer's pick-axe while excavating for a new subway which crossed an existing subway. It is related of the laborer that when he saw the smoke arising from the burning insulation he first tried to put out the fire by throwing water over the cable and subsequently by throwing wet mortar around it.

It is perhaps not remarkable, in view of all the circumstances, that anything in the shape of an electric wire is looked upon by outsiders with serious apprehensions. It has sometimes been amusing to notice the wide berth given even the leading in wires used during the making of tests of cables, by the occupants of buildings from which the test is being made.

On one occasion while a test was being made in the basement of the Hotel Brunswick, it happened that the lead wires were lying on the floor near by a small pool of water in a hallway. A servant seeing the water and the wires in close proximity called out in alarm to one of her companions who was approaching, "Take care Mary, the electricity is running out."

DEFECTIVE CABLES.

In the case of the cable previously referred to as having been abandoned, the burn-outs were of almost nightly occurrence. The delays to the company using this cable were necessarily vexatious, and I may say that in my references to burn outs, defects, etc., occurring in underground cables, I have not included those that were due to the use of this seemingly inherently defective cable. This was a lead covered cable with a vulcanite tube as an insulating medium. This special cable has been abandoned, and is no longer in service in the New York subways. What may appear a singular feature in connection with the burn-outs in this cable was the fact that it had a higher apparent insulation resistance than any other cable in the subways, and would frequently on a test show an insulation resistance of over 4,000 megohms per mile, a few hours before the occurrence of a burn-out. The same cable showed even a higher test at the factory, namely, about 20,000 megohms per mile. In the latter case it was tested with 400 volts. Burn-outs on this cable have occurred when the pressure employed on the circuit did not much exceed 600 volts.

The explanation of this may be that owing to the nature of the insulating material and to the fact that it was not tested under water before being lead covered, there may have existed fractures in the tubing, or such fractures may have been caused in process of drawing the cable into the ducts. Under the tests made with the 100 and 400 volts E. M. F. of the testing battery the fault would not develop; under the high electromotive force of the dynamo and the current of 10 or 12 amperes, the fault would develop; perhaps due to moisture of condensation of the air in the tube caused by the heating of the wire. This explanation is apparently confirmed by the fact that 25 miles of a somewhat similar cable, namely, the Cobb cable (which I have described), but in which paraffine is placed between the lead covering and the vulcanite tube, has been in successful operation in the subways for high tension currents for over two months without any indication of a defect having occurred.

It was rather unfortunate that the type of cable which I have said has been abandoned as unsatisfactory and which has indeed been withdrawn from the subways, appears to have been the only cable used for electric lighting purposes in the New York subways, which came to the notice of an English electrical engineer, during a flying visit to this country, and a description of which cable he presented to our sister society in London in a recent paper with a favorable prediction as to its probable success.

LOCATING FAULTS.

The method employed for locating faults in electric light conductors in the subways, is to test the conductor from point to point until the defect is placed between two lamps or man-holes. When a fault is located between two lamps or two man-holes, if it is in the cable proper and not in a joint at a hand-hole or box, the defective section is withdrawn and a perfect section put in its place. With the exception of the hard rubber cable referred to, this has, I believe, been necessary but on three occasions after the current has been turned on the circuit; in two of these the defects were caused by improperly made joints. In the other case by a mechanical injury.

In the case of arc light or series circuits, defects in the cables are more readily located than in multiple arc circuits, because of the facility afforded by the openings at the lamps for testing the conductor in sections. In the case of multiple arc circuits there is at present no means of locating faults but by cutting the conductor in man-holes. For, as the house connections are made from the cable by T joints, it is obvious that the only effect of disconnecting the lamps or converters from the cable is to separate the two conductors of the circuit. These remarks, it is understood, do not apply to the Edison conductors, to which, it is well known, access is had at the ends of each pipe, by removing the paving and earth above the pipe.

No attempt is made to locate faults in electric light circuits in the subways by electrical measurements, for the reason that the obstacles in the way of obtaining accurate data are so numerous that it has not been considered expedient to rely on the results of such measurements. For instance, the uncertainty as to the distribution of the resistance of the conductor, owing to the numerous joints in the circuit; the variations in temperature of the subways and the difficulty in ascertaining it, etc.

To facilitate the locating of faults, should they occur in the subways, several forms of accessible joints have been suggested for use in the man-holes. One of these known, I think, as the Dillon joint, consists of a metal cup having in its bottom apertures through which the cable ends pass. The lead covering of the cable is soldered into the cup, the conductors are connected or spliced and insulated when a water tight cover is screwed over the cup.

Another accessible joint, known as the Cobb joint, is made as follows: A copper disc is soldered on the ends of the conductors to be connected. Over the discs a vulcanite sleeve is placed. Two shoulders having respectively a right and left hand screw are placed, near the sleeve, over the insulation of the conductor. The sleeve is provided with a right and left hand thread. The forward movement of the shoulder is checked by the discs on the ends of the conductors. Thus when the sleeve is screwed on to both shoulders the tendency is to press the two discs together tightly. This joint can be made quickly; but as to its practical utility it is not possible to speak definitely as yet, since it has not been in actual service in the subways, so far as I am aware. The same is true of the Dillon joint.

It is, perhaps, a debatable question whether easily accessible joints are desirable in the man-holes of subways, as the tendency in such cases might be to lead to accidents by the exposure of live wires.

DURABILITY OF CABLES.

Concerning the much discussed question as to the relative durability of rubber compound and fibrous cables, I do not think sufficient time has elapsed in the case of the cables in the New York subways to enable one to arrive at a definite judgment. In the case of both types of cable, as I have already said, many circuits have been running continuously for over nine months, and in some instances for over one year, without a defect of any kind, electrical or mechanical having occurred, and the slighter defects that have occurred on other circuits have as yet been so few in either type of cable as not to certainly show any marked superiority of one type over another. Specimens of cable that have been examined after nine to twelve months service show no physical or electrical signs of deterioration of the insulation.

As regards the question as to which kind of cable will best withstand the heat from steam pipes adjacent to the subways—it would appear thus far that the lead covered fibrous cable is superior to the homogeneous cable *not* lead covered. Lead covered rubber compound cables have not as yet been tried in the heated districts.

MULTIPLE CABLES.

These are no concentric cables in the subways in this city. The mains of multiple arc circuits are operated in separate lead covers in the same duct. It is contemplated, I believe, by some of the companies to use one lead cover for such circuits hereafter. One objection on the part of the companies to the use of concentric cables is the anticipated difficulty in making joints, especially where frequent connections for distribution are required. This objection should not hold good in the case of the feeder portion of the circuits.

As to the use of multiple cables for electric lighting. One such cable—a fibrous cable—having eight conductors under one lead cover was placed in the subways but has not been operated as yet, trouble having been found in making perfect joints. I have no doubt that with the experience since had in joint making, this difficulty would be overcome; but it seems to be the general opinion that the use of multiple cables is not advisable in electric lighting.

On the subject of loss due to increased electrostatic capacity or to increased self-induction of conductors in the subways, I may say that I have made careful inquiry of superintendents of stations where the alternating current is used, and learn that no perceptible difference in the operation of the circuits as compared with similar circuits overhead is noticeable. I have been informed that in wet, stormy weather a decided improvement is observable—in fact that the condition of the weather does not affect the circuits. This will be readily understood when it is stated that a recent test, made during the prevalence of a drenching rain storm, of an arc circuit in the subways four miles in length, showed an insulation resistance of 2,400 megohms per mile. The lamp connections were disconnected from the cable proper during the tests, so that the entire cable was under cover except at the pole.

JOINTS.

When it was being urged upon the electric light companies of this city, that they were not using due diligence in placing their wires underground, the companies retorted that they were doing so as rapidly as it was possible, consistent with good workmanship, and stated that it was not possible to joint up the cables more rapidly than was being done with the number of capable jointers at their command. To this an official of the city replied, that this did not, in his opinion, constitute a valid excuse while so many poor men were idle who would be only too glad to be given work at jointing the cables.

This was the view of a layman, but it would seem that in a number of instances in the electric light service in this country a similar view, namely, that anyone could make joints, and that any kind of joints might be made was held by those who should be supposed to know to the contrary.

In this city, I think, it is now fully recognized, by the electric light companies at least, that it pays to employ good jointers in underground work.

Several forms of joints are used on the electric light cables in subways, among them one known as the rubber joint. It is sometimes termed the half marine joint. This joint is made practically as follows: First the lead covering is removed for about three inches from the end of the conductor. About one inch of the insulation is then removed from the ends of the conductor, the ends of the conductor are then "sweated" together. Generally a split copper sleeve being placed over the ends. When a T joint is to be made, a T sleeve is used. This facilitates the making of the joint by dispensing with filing the ends of the conductor and then wrapping them with small wire. No acid is used in the making of the joint. Resin is commonly used as a slag. After the wire has been spliced, the insulation is then scarfed for about three-quarters of an inch, when a layer of pure rubber strip is wrapped around the wire spirally back and forth about three times, and each time the rubber is brought further up the scarfed insulation. A few layers of white rubber strip is then wound above the pure rubber strip and after that a layer or two of pink rubber strip. A layer of fibrous rubber tape is then put on over all. Between each layer of rubber strip a small quantity of rubber solution is put on to make the rubber adhesive and practically homogeneous. A lead sleeve is then placed over the joint and wiped on to the lead covering. This joint can be made in about 20 minutes, exclusive of time taken in wiping the lead sleeve. This joint is used altogether on the "Bishop" and the "safety" cables. Also, occasionally on the Standard and Cobb cables. But as a rule the Cobb people make a special joint somewhat as follows: The ends of the conductors are spliced in the usual way, a hard rubber ferule having first been placed over one end of the conductor and a brass ferule over the other conductor, above the insulation. A machine like a double vise is then placed over the lead covering of the cable and made fast thereto. A tightening device next draws the ends of the vulcanite together, taking up slack in the cable. The vulcanite sleeve or ferule is then welded by heat to the vulcanite tube, after which the brass ferule is drawn over the tube. A mould is then placed around the joint into which molten lead is poured, thus casting a solid lead sleeve. This is quickly cooled by the application to the mould of cold water. The mould is then removed and the joint is complete. This form of joint has been found satisfactory, I believe, and it is claimed that it can be made in much less time than a half marine joint.

The joint chiefly used on the Standard Underground cable is made differently from either of the foregoing. After the conductor has been spliced as usual and the lead covering has been cut back from the insulation, a few turns of tape is passed around the splice. A leaden sleeve is then put on over this and wiped firmly to the lead cover of the cable. When this has been done a couple of small holes are punctured in the lead sleeve through which a boiling insulating compound, used in the manufacture of the cable, is poured, filling up the sleeve completely, after which the holes are closed by solder. These joints have been found to give excellent service on this form of cable. The time taken in making this joint is about 30 minutes.

LEAD COVERED CABLE.

The cables used in the electric light service in the New York subways are, as I have elsewhere stated, without exception lead covered. In the case of fibrous insulation, this is essential to exclude moisture, but not in the case of the rubber cables except as a protection against gas and acids, and, to a certain extent, mechanical injury. The use of this lead covering is not required by the subway rules. In addition to being a protection against the attack of acids and gases, the lead covering is considered a safeguard against accidents to men working in the man-holes amongst live wires. For, if a defect should occur in the insulation in the man-hole, the presence of a ground furnished by the lead covering would make the defect known at the regular test, which, if the defect were of a serious nature, would ensure its being located and eliminated. Whereas, if the conductor were not lead covered there is a probability that a defect in the insulation might occur that would not be indicated by the test, but which might expose the conductor and render it impossible for workmen in the man-holes to make contact therewith. It would be quite possible for a workman to handle the lead covering of even a defective conductor without injury since the lead covering is grounded throughout the length of the subway.

It will hardly be credited by some people, but it is a fact, that live electric light wires conveying the alternating high tension arc currents are handled and moved about in the man-holes by means of the lead covering without the slightest indication that such wires are alive. In fact, it is quite a common occurrence to start up alternating circuits immediately after a rubber joint has been made in order to save time, and then to have the plumber adjust and wipe the sleeve on to the lead cover while the current is in full operation.

Another fact is this, that in the subways, no shocks whatever due to induced currents in the lead covering are felt by the workmen in handling the lead covered cables conveying the alternating current. It is quite conceivable that such shocks might be noticed, as I believe they are, where the cables are suspended from point to point and insulated. In that case, any one handling the lead covering of the conductors would doubtless receive the accumulated induced charge.

It has been stated frequently that such induced currents, where the lead covering of the conductors is insulated, have been known to injure the lead covering and eventually to destroy the insulation.

So far as I have been able to ascertain, not in a single instance has such an action taken place in the subways.

As a matter of fact, close personal observation and careful inquiry on all sides have failed to discover thus far any sign of deterioration in the condition of the material of the conduits; the lead covering of the insulation or of the insulation of the cables in the subways, with the exception of the effect upon the lead covering of the telephone cable in the creosoted wood conduit, referred to. I may add that even in the latter case, personal inspection and inquiry made of workmen, have not confirmed the statement that the lead covering had been attacked. At all events there is no evidence of any such wholesale manufacture of white lead as has been reported from other places where lead covered cables have been placed in creosoted wood boxes.

INSULATION AND TESTS.

The requirements of the rules of the Subway company as regards insulation are such that none but a first-class insulation can well be employed on the conductors conveying currents of high electromotive force. These rules require an initial insulation resistance of 15 megohms per mile per 100 volts electromotive force employed on the circuit, and a minimum of 5 megohms per mile per 100 volts. The initial test is made when the conductor is first laid in the subway and prior to the turning on of the current. The minimum requirement is allowed after the circuit has been in use. This insulation requirement refers to the conductor proper in the subway, and does not include the lamps, aerial connections or converters. The rule does not apply to conductors conveying currents of less than 100 volts E. M. F. In the case of alternating circuits, the uniform electromotive force employed in this city being 1000 volts, the conductors to be employed in this service are required to show an initial insulation resistance of 150 megohms per mile, and a minimum insulation resistance afterwards of at least 50 megohms per mile.

The average E. M. F. of the arc light circuits in the subways is about 2,000 volts; but in some instances it runs up to 3,500 volts. In the latter case, the initial insulation resistance required by the rules is 525 megohms per mile. Minimum, 175 megohms per mile.

It was first thought by many, that it would be impossible to maintain even the minimum insulation resistance required by the rules, and this supposed impossibility was cited by some of the electric light companies as an instance of the impracticability of the proposition that they should utilize the subways. The representative of one such company very naively stated that it would certainly be impossible for his company to maintain this insulation if compelled to go into the subways, as the insulation the company used in its service was "underwriters'." One of the experts of the same company, in his evidence, repeated the very common remark that one megohm, *if it could be maintained*, would be quite sufficient for practical purposes. I do not think that this statement will be seriously contradicted; but the difficulty is to maintain the insulation at one megohm in practice. Experience in the New York subways has shown that it is vastly easier to maintain the insulation resistance at 150 and even 500 megohms per mile than it has been in the past in other cities to maintain them at one megohm per mile. A gentleman writing of the Chicago underground system, not quite two years ago, remarked: "It was found that although the insulation measurement of the lead covered cables in the conduit was very high, considerably above a megohm, a short circuit would form generally within 1,000 feet of the station between the two sides of the circuit."

The explanation for this short circuiting under such conditions would appear to be simple, namely, that if the insulation resistance of a conductor is but one megohm per mile, the covering being of the ordinary thickness, it is clear enough that it is decidedly inferior insulation, and if the normal insulation resistance of the conductor is very much higher than one megohm per mile, but the measurement nevertheless shows it to have an insulation resistance of but one megohm, it is or should be sufficient evidence that a fault has developed in the insulation which need surprise no one when it produces a short circuit or burn out.

As I was in no wise responsible for the promulgation of the subway rule which places the initial and minimum insulation resistance of the electric light conductors at the figures given, not having been connected with the company in any capacity at the time the rule was authorized, modesty need not restrain me from saying, that experience of over a year has amply proven the wisdom of those requirements. For these requirements not only necessitated the use of an insulating material possessing high specific insulation, but also compelled the exercise of the greatest care in the details of placing the conductors in the conduits, in the making of joints, etc.

When it is stated that these conductors are jointed at every man-hole, and in many instances at several places between man-holes, the need of such carefulness in order to maintain a high insulation will be understood.

If, for example, the method of making joints, that it is related was employed some years ago in Philadelphia, namely, to strip the ends of the lead covering for two or three inches, and then to place three or four turns of tape around the ends of the conductor, had been followed in the New York subways, and had been permitted in the absence of the rules referred to, I make no doubt I would have had to report to-night a continued series of failures in the electric light service similar to those so often quoted as having happened in Philadelphia. I am confirmed in this belief by the fact that the first electric light conductors laid in the New York subways were found to possess an insulation resistance of but little over 100,000 ohms. This, notwithstanding that the insulation resistance of the conductors at the factory was over 2,000 megohms per mile. There were about 40 joints in these conductors. Where these had been cut out and new ones made by an expert jointer, the insulation resistance rose to over 1,500 megohms per mile, and a very recent test of the same circuit shows it to possess virtually the same insulation resistance.

Under the methods once in vogue in other cities in this country with regard to underground work, in which no tests for defects were made excepting for such as would be indicated by an ordinary magneto, the circuit I have referred to would have been put into operation without question, and there is, I think, not much doubt as to what the outcome would have been.

The high tension electric light conductors are tested weekly for insulation resistance. The tests are made by the direct deflection method. A Thomson reflecting galvanometer being used, and as a rule 100 cells chloride of silver battery is employed as a testing battery. The tests are generally made from some room or basement adjacent to the terminals of the conductors in the subway, in order that the subway portion of the circuit may be tested exclusive of aerial portions.

At present the subways do not extend to the electric light stations, although in a very short time they will do so, as in the case of the Stanton street United States Illuminating Co.'s station.

When the conductors emerge from the subways they are run through subsidiary iron pipes up the side of a pole. From this pole the lead wires are run to the testing room.

The subway conductors are, as a rule, tested exclusive of arc lamps, converter, and inside wiring, but frequently also the tests are made inclusive of arc lamps and converters. These latter tests are only accepted when the results fairly indicate that the fall of insulation is due to the lamps or converters. In quite a number of cases the tests with converters included show an insulation resistance up to the requirements.

Tests of circuits are not made inclusive of house wiring because of the generally low results of trial tests. Some such tests that I have made showed an insulation resistance of the house wiring of less than 1,000 ohms.

The following records of actual tests may be of interest:—

Circuit A.—Arc. Initial test, 588 megohms per mile. Last test of same circuit, 388 megohms. Present length of circuit, 9.5 miles.

Circuit B. Alternating. Initial tests, 141 megohms. Last test, 1,250 megohms. Length, 9.6 miles. The first test was made when circuit was much shorter than at present, and doubtless the terminals of conductor were exposed during that test.

Circuit D.—Initial test, Jan. 6, 1889, 424 megohms per mile. Subsequent test, Jan. 2, 1890, 484 megohms per mile. Length of circuit, two miles.

Circuit E. Jan. 4, 1889, 1,750 megohms per mile. Same circuit, Jan. 4, 1890, 1,516 megohms per mile. Length, one mile.

Circuit F. July 7, 1889, 264 megohms per mile. Jan. 3, 1890, 343 megohms. Length, 6.6 miles.

The readings for these tests are generally taken after one or two minutes' electrification.

Tests with converters included in some cases, show very fair insulation. One circuit, with 34 converters included, showed 11 megohms insulation resistance. Another, with 11 converters included, gave a total insulation resistance of 159 megohms. It is not uncommon to get an insulation resistance of from two to five megohms with 30 and 40 converters in circuit. These tests did not include aerial portions of circuits. It should be said that the insulation of the converters and connections is being constantly improved; and, in my opinion, the time is not remote when the underground circuits will test up to requirements at all times with converters included.

As all of the conductors of the same company do not terminate at any one point, and the instruments have to be moved from place to place, the apparatus used in making the tests is of a portable pattern. The entire outfit can in an emergency be carried by one person, and very readily by two persons.

Contrary to the expectations of some people the actual making of these electrical tests has not been attended with any serious difficulty. The most troublesome factor has been that due to surface leakage at the battery or other parts of the testing equipment, during the very humid weather which prevailed so continuously last summer and winter.

The time for making these tests is, as far as possible, chosen to suit the convenience of customers. The majority of the tests are now made in the early mornings. All circuits are tested once a week at least.

About 130 miles of the subway electric light converters referred to are employed as carriers of alternate current for incandescent lighting. About 60 miles as carriers of arc light and incandescent continuous currents. The circuits vary in length from one mile to 11 miles, the longest arc light circuit is 10 miles in length; the longest alternating circuit is 11 miles in length. In 10 miles of alternating or arc circuit there are from 450 to 500 joints. The greatest number of converters on one subway circuit is 65. There are 14 arc light circuits and 25 alternating circuits in the subways.

Quite recently an alternating arc circuit has been installed in the subways which is intended to be the pioneer of numerous such circuits. I may say that it is ultimately intended to operate at least 125 lamps in such circuits.

LIGHTNING ARRESTERS.

In the case of many of the electric light conductors that were first laid in the subways of New York city, lightning arresters were used at street lamps and at the terminals of the cable, and in a number of instances the same apparatus is still used. These "arresters" are those known as the Acheson cable protector, and are intended to protect the cable against disruptive discharge from any source. The principle upon which the device is intended to act is that the disruptive discharges, or what would be the disruptive discharge, will jump the air space between the points of the needles, thus relieving the cable from the strain. The utility of this device for the purpose intended has yet to be demonstrated in this city, inasmuch as the frequency of burn outs in unprotected cables in the subways has been no greater than in those which are equipped with the protector, the percentage of burn outs on cables in either case being, as I have before intimated, very low. It is as yet, I think, an open question, whether the use of this or any equivalent device is warranted. There is no record of any of the cables in the New York subways having received injury from lightning during the past year.

It is commonly supposed that the freedom from burn-outs which the successful electric light cables in the New York subways have enjoyed, as compared with the earlier experience of other cities, is due to an increased thickness of insulation around the conductor. This may be the correct explanation; but the fact is worthy of attention in connection with this subject, that certain electrical condensers have for years been placed in positions where they are exposed to the full effect of lightning discharges on telegraph lines without, in a single instance, having sustained injury therefrom. Similar instruments have also been placed across the poles of 1,000 volts alternating dynamo machines for days without perceptible harmful effect. Since it is difficult to imagine a better opportunity for a disruptive discharge to effect its escape to earth than that presented by the extremely thin tissue paper used in those condensers, the thought is suggested that if this paper can be so constructed as to act as a barrier to the passage of such charges there may be more to be considered in this matter of insulation than the mere question of thickness of the insulating material.

ALLEGED DANGERS OF THE SUBWAYS.

The dangers to be apprehended from the existence of the electrical subways and from the placing of the "high tension" wires therein (according to those who are perhaps more or less inimical to that action) are varied. In general terms, they say, that the dangers which menace the public and employés from the presence of wires overhead will be multiplied manifold when the wires are underground. But when asked to specify those dangers the reply is limited to the following, namely, first, that linemen will be killed by coming in contact with live wires in the man-holes; second, that high tension currents will leave the subways and enter buildings by way of water and gas pipes, etc.; and third, that accidents due to explosions of gas in the subways will be numerous.

As regards accidents to workmen in the man-holes due to contact with live wires, no one will say that such occurrences are impossible, but inasmuch as not a single accident of this kind has occurred in New York city, or, so far as I can learn, elsewhere, in electrical subways, it is fair to assume that, with the exercise of proper supervision of the wires this is not likely to prove a frequent source of accident. I was present at the inquest of one of the unfortunate linemen who was killed last year in New York city by contact with an overhead wire, when a witness who had just made the statement that he apprehended more accidents from the placing of wires underground than had occurred overhead, was asked if he was aware that there were at the time about 100 miles of electric light wire underground in New York city conveying high tension currents and that not one accident had thus far occurred in the man-holes; to which he replied that this state of things was explainable in his opinion by the fact that the electric light wires underground constituted but one tenth of the electric wires of the city, and that when all the wires were underground the accidents in the subways would increase in the same proportion—which reply caused the foreman of the jury to remark that the public would probably not complain of an increase of accidents from nought to ten times nought.

I have already suggested in another place, that the fact of the wires being metallically covered may have conduced to the immunity from accidents which the workmen in the man-holes have enjoyed. I may interpolate here that it is recognized that the efficiency of the man-holes would in many instances be increased if they were larger, and whereever the surrounding condition of the street will permit, it is, I believe, contemplated to enlarge the man-holes.

So far as the statement is concerned, that danger is to be apprehended by the entrance of powerful currents into buildings by way of water and gas pipes, by contact of a grounded conductor in the subways, it would scarcely be worthy of notice before a body of electricians but for the persistency with which it is said to be urged by men of prominence in the electrical profession. It is conceivable that if a conductor, within a building, should by accident come in contact with a well insulated gas pipe also within a building, one might receive a shock by contact with the gas pipe if in some manner he should complete the circuit, but in what manner, in the event of a ground in the subways, any dangerous current can be conveyed to the inside of a building by means of gas and water pipes which have the entire area of the city's foundation as a ground or return circuit is more difficult to understand.

But whatever may be the dangers, stated or unstated, so freely predicted as liable to occur with the wires underground, it may certainly be said that with the electric wires underground men will not be injured by falling off poles in the subways. Wires when in the subways, during the prevalence of sleet storms, etc., will not fall upon people or horses in the street, nor be torn down by elevated railway trains, street cars, etc.

GAS IN THE SUBWAYS.

In my opinion, the presence of gas is the most serious defect of electrical subways in cities; of course it is not an inherent defect in the subways, but it is nevertheless a very troublesome one, not only because of the danger of explosion therefrom, but also because of its ill effects upon workmen employed in the subways.

As previously remarked, the ducts used in the subways are not only joined together as nearly hermetically as possible, but, except in the case of distributing ducts, they are laid in a solid body of cement from man-hole to man-hole. It is supposed that the gas obtains ingress to the man-holes through the place where the iron man-hole cover rests upon the masonry of the man-hole. But at whatever point the gas enters the subways its unwelcome presence is acknowledged, and while it is self-evident to any one who will investigate the matter for himself, and is actually admitted by the gas companies, that the gas emanates from the gas mains in the streets, nevertheless the subway engineers have been constantly at work devising means to remove the intruder.

To this end various methods for ventilating the subways have been suggested and tried, the most successful of which thus far has been the ventilation of the subways by the use of blowers stationed at intervals along the subways, and arrangements are now in progress to place 15 such blowers in operation to cover the entire subway system.

As the ducts become filled with cables, however, the free passage of air through them is prevented and in this way the utility of the blowers is diminished. In order to evade this difficulty, a six-inch wrought iron pipe has been laid above the subway ducts in the more recently constructed subways. This large iron pipe has openings at each manhole. The openings are graduated as to their extent as they recede from the source of the air pressure. The large openings are at the points remote from the blower. It is intended by the use of these large pipes to furnish a counter pressure in the subways somewhat exceeding any tendency of a pressure from the outside, rather than to produce a strong current of air through the ducts, and in this way to prevent the ingress of gas through any crevices that may exist in the subways.

It has been frequently suggested that good results might follow a suction method of ventilation, but experience has shown that this would rather aggravate the evil, as it would draw into the subway all the accumulated gas in the streets besides inviting a larger leakage from the gas mains.

The only beneficial effect to the subways of this resort to blowers to drive out the gas is that the air dries up the ducts and man-holes within quite a distance of the blowers.

The cause of these explosions in the subways has not in every case been definitely located. It is known that they are due primarily to the ignition of an accumulation of illuminating gas mixed with atmospheric air in explosive proportions; but the difficulty has been to ascertain by what means the gas has been ignited. It is on record that these explosions have occurred in sections of the subways in which there were at the time no wires whatever. And in cases where there have been live wires in the vicinity of an explosion, tests made immediately after the event have shown that those wires were in perfect condition as regards insulation. There are but three instances on record in which a defect in an electric light cable has occurred simultaneously with an explosion in the subways, and in one of these cases the defect occurred so nearly incidentally with the explosion that while it is quite possible that the defect may have caused the explosion, it, the defect, may have been due to mechanical injury due to the explosion.

Among other theories it has been suggested that the gas may be ignited by currents, induced in the lead covering of alternating current conductors. This might be the case if, as I have before suggested, the cables were supported from beam to beam, as on a bridge, on insulated stands, and if the lead coverings only approached each other at intervals, but where the lead coverings of the conductors are not only grounded throughout their lengths in the subways, but are also joined metallically, in fact are practically one cable in the ducts, it seems unlikely that a quantity of induced electricity sufficient to produce a spark could be accumulated at any one point.

In the case of at least two explosions in New York city, the evidence showed that the gas in the subways had been ignited by a lighted lamp or match in the vicinity of some subsidiary duct connecting with the subways. In other instances by a match or lighted cigar thrown in a man-hole. It is known that in Chicago an explosion was caused in the subways by a live coal from a passing fire engine, falling upon the cover of a man-hole.

With but one or two exceptions, the explosions have not injured the cables in the subways; which is probably due to the small and round surface which the cables present.

It has frequently been suggested that if solid ducts were employed instead of tubular ducts these explosions would be avoided. While this would be, if correct, a strong argument in favor of solid conduits, that is, ducts in which the conductors are not removable, notwithstanding the generally admitted fact that such ducts are not practicable for subway work on a large scale, experience has demonstrated that explosions have occurred repeatedly in man-holes and in small junction boxes of subway systems in which there were no hollow ducts.

I may add, that pending the installation of blowers in certain of the subways, men are employed day and night opening man-holes to permit escape of gas.

I had intended to comment briefly on the comparative expense of maintenance and reliability of underground wires in cities as compared with overhead wires, but as my paper has far exceeded the limits which I had placed upon it, I shall leave that and other features in abeyance for the present. Perhaps something bearing on those points may be brought out in the discussion.

The following are some of the rules of the subways of New York city which have been promulgated as precautionary measures or as a result of actual experience:—

No bare ends or bare portions of conductors, whether in or out of service are permitted in the man-holes. Every conductor in the man-hole is treated as though it were operative.

No joints except such as are protected by a metallic covering are permitted in the man-holes.

No lights are allowed in man-holes.

All conductors in man-holes are required to be arranged symmetrically around the walls and to be plainly tagged with the designating mark of circuit and the name of the owner. One of the pictures (which I have, by the courtesy of Mr. Beckwith, the chief engineer of the Subway company, been able to procure from his office) shows the cables passing through the man-hole in rather a haphazard way. This would do where there are but one or two conductors in the conduit, but when the conductors multiply, an orderly arrangement of them is essential.

No switch boxes are allowed in the man-holes. The reason for this is, that in the first place a switch box for each company would take up too much of the limited room; and secondly, in the case of electric light circuits it is feared that attempts to switch live circuits might produce dangerous sparks in the man-holes.

In conclusion, I think, it may be said that the experience derived from the practical operation of the electrical subways of New York city, has either made apparent or confirmed among other things the following:—

That it is possible to successfully operate all classes of electric conductors underground in cities.

That, at least for conductors conveying high tension currents underground, it is advisable to set the standard of insulation high.

That regular insulation tests of the conductors are very valuable.

That liberal thickness of insulation is desirable for high tension currents.

That it is unadvisable to place underground new types of cable or insulation until they have been subjected to tests and conditions analogous to those to which they will be subjected underground.

That for electric lighting conductors—especially distributing mains—many conductors under one cover are not advisable owing chiefly to the difficulty in making joints in such cables.

That all sharp edges in ducts should be avoided.

That until the gas light companies are required, like the electric light companies, to maintain their mains in a fairly sound condition underground, a means of ventilating the subways should be provided simultaneously with the construction of the subways.

And lastly, that while other features may be accessories thereto, the employment of smooth strong conduits, accessible ducts for distribution of the current, first-class insulation, constant expert attention to details and thorough organization in every department, are essential to the production of a successful electrical underground system.

ON MUSCULAR CONTRACTIONS FOLLOWING DEATH BY ELECTRICITY.[1]

BY PROFESSOR EDWIN J. HOUSTON.

Accurate data are wanting as to whether death resulting from accidental contact with electric conductors conveying the powerful currents employed in systems of electric lighting or power distribution is, or is not, practically instantaneous. Certain facts, however, are known which show that when the nature of the contacts is such that the discharge passes through the respiratory, the cardiac or the brain centres, that true physiological death, as evidenced by the complete failure of these centres to perform their normal functions, and their inability afterwards to perform these functions, is practically instantaneous.

In cases of death from a lightning bolt, for example, instances are on record where death has been so nearly instantaneous that the bodies have remained so nearly in the positions occupied during life that passers-by have failed to recognize the presence of death.

On the regaining of consciousness lost by a lightning discharge or a contact with an electric conductor, the subject, as a rule, has no memory of pain or suffering, and in many instances is even ignorant of the cause of the accident.

A fact, however, which appears to disprove that practically instantaneous physiological death follows a powerful electric discharge, should be alluded to. In some instances, it has been observed that the body of the person receiving the discharge, showed prolonged convulsive muscular contractions and contortions. The question thus arises, Do such muscular movements necessarily prove actual suffering on the part of the subject? Do they even necessarily prove the existence of life while they are taking place? While, of course, the answer to this question must necessarily be to a certain extent uncertain, the following considerations are offered to show that in all probability such muscular contractions follow physiological death, and are, therefore, unattended by consciousness or suffering.

---

[1] Read before the American Philosophical Society, February 7, 1890.

Two general cases of contact resulting in death may occur, viz.:—

1. A momentary contact, where the discharge is only temporary, as in the case of the lightning discharge, or the case of a person falling against the wires and remaining in contact therewith but a few seconds or fractions of a second.

2. A prolonged contact where the current continues to pass through the body for some time after death.

In cases of death by the first class of contacts, no convulsive movements occur. Death results from physiological shock, or possibly from changes in the nervous or muscular tissues.

In the second class of contacts, death in many cases probably occurs practically instantaneously. The question then arises, How can the muscular contractions be explained?

The classic experiments of Galvani with the excised legs of recently killed frogs, prove conclusively that the passage of an electric current causes convulsive muscular movements. The same phenomena, too, have been observed in the human subject, as numerous experiments with the bodies of criminals shortly after their execution have shown.

It would seem, therefore, probable, to say the least, that when the electric current continues to pass through the body of the subject after physiological death has occurred, such convulsive muscular movements may occur, and that, therefore, their existence do not prove suffering.

When a powerful current traverses the body, tetanus occurs, and muscular movements in such parts cease. The nerve loses its sensibility, and, if the current is too strong, changes occur in its structure or composition, either as a result of polarization, or electrolysis, or otherwise, which prevent it from being further affected by the electric discharge. Since such changes presumably occur in cases of death by electric discharges, it would appear that muscular contractions would therefore be impossible after death. A brief consideration of the manner in which an electric current traverses the human body will show that such a conclusion is unwarranted.

When the electrodes of any source are applied to any two parts of the human body, a current passes through the body from a positive to the negative electrode. The density of current that passes, or the current strength per unit of area of cross-section, is different at different parts of the body. Those portions that lie in the paths of least resistance, which, in general, are situated in paths of least distance between the electrodes, receive the denser and more powerful current, while those lying in paths of greater resistance, receive weaker currents. In other words, in the passage of the electric current through the human body, a diffusion of the current occurs.

While, therefore, the nerves and muscles lying in the direct path of a fatal discharge may be almost instantly deprived of their sensibility by the passage of the powerful and fatal discharge through them, the nerves and muscles which lie in the paths of less powerful currents may still retain their power of electric excitation.

It is therefore probable, that in cases of prolonged fatal contact with electric conductors, the ensuing convulsive muscular contractions do not of necessity prove suffering.

I offer these views with some diffidence from the standpoint of an electrician rather than that of a physiologist.

.... FACTS form the wall around the fortress of knowledge against which the arrows of theories and false conclusions fall harmless.—*Foree Bain.*

Papers Read at the Convention of the National Electric Light Association, Kansas, Mo., Feb. 11--14, 1890.

SAFETY AND SAFETY DEVICES IN ELECTRIC INSTALLATIONS.

BY PROFESSOR ELIHU THOMSON.

THE development of the electrical arts, particularly in the direction of lighting and motive power transmission, has, in the past few years, been very great. It has brought with it a demand for very much work of a novel character, as regards the details of plant and methods of installation. It has also entailed, in many cases, elements of risk to life, and danger of fire. How far these risks have been or can be removed by proper attention to details and care in installation, has become an important subject for discussion. How far such risks have been increased by reckless installation of conductors, by faulty materials and supervision, it is not easy to determine. There can be no doubt, however, that electricity, as an agent, in itself is not to be charged with bringing about the results for which recklessness in its use is sufficient to account. That under favorable conditions for discharge through a person's body, electric currents of comparatively high pressure may injure or kill, is not to be questioned for a moment. I have no sympathy with any effort tending to impress a false estimate of such risks, or tending to give the impression that they are absent, when in reality they are existent. I have no sympathy with any efforts to exaggerate such risks, efforts which have not been wanting, indeed, as is well known. The fire risk, as well as the personal risk, involved in electric work is present in a greater or less degree, in accordance with the perfection of the work of installation and maintenance, the provision of the proper safeguards, and selection of the best conditions.

These are matters which are, every-day, of growing importance in all the electric industries, not even excepting telephonic systems and other such work, which, if badly arranged and not properly maintained, may cause crosses due to falling wires, etc., to become sources of danger, trouble and annoyance in the distribution of lighting or other currents. There is one fact which is of the greatest importance in this connection, and it is that safe installation means, also, good service. There can be no question that the risk to life *from shocks*, even with bad work, would be removed by not using high potential currents, as they are called, either alternating or direct. There can be no question, also, that a shock obtained from certain characters of current, such as an alternating current, is much less safe than in the case of continuous currents of equivalent pressures. Nevertheless, I am just as firmly convinced that the fire risk is very much less with alternating than with continuous currents of equivalent potential, assuming the work of installation equally good. The fact that it is difficult to sustain an arc, or rather that it is easy to select conditions which will prevent arcs forming with the alternating system, as compared with the continuous current systems of much less potential, is greatly in favor of the former. Hence switches, fuses, bad joints, ruptured wires, are much less liable to arc and incur risk of fire with alternating than with continuous currents. Would it be possible to work successfully, using only low potential currents of either character? Would we be able to utilize water powers for lighting, without employing pressure of potential sufficient to convey the energy to a distance over a conductor of moderate or non-prohibitive cost? In most cases we would certainly not be so able. Again, to utilize water frontage for cheap coal supply, and to employ compound condensing engines, to ensure small running expenses by massing the machinery at one station, to make use of railroad facilities, etc., in short, to work under the most advantageous operative and economical conditions, we *must* convey electrical energy by moderately high electric pressures, so as to avoid prohibitive losses or prohibitive cost of conducting wires. If ever our great natural resources in water powers are to be developed and utilized, it will be by the employment of comparatively great electrical pressures for conveyance of energy to distant points. If great saving of cost of fuel and other expenses in operating one large steam plant, instead of a number of separate plants, with their attendant risks, in large cities, is an object worth seeking, it will be found in the conveyance of electric energy at fairly high pressures. It must not be forgotten in this connection that even with very low pressure currents, safety from fire risk is only to be secured by careful construction and supervision, and that risk of fire often involves personal risk. Subway and underground conductors have caused man-hole explosions, with both low and high potential currents. Such accidents are generally explained by accumulations of coal gas formed in the man-hole and subsequently fired by the electric arc or spark of a leak. This may be and probably is sufficient explanation, but another may be given—the evidence of the possible correctness of which I have witnessed. A heavy leak or overheating occurring at some point of the conductors near the man-hole, may generate directly a large volume of inflammable gas from the distillation of asphaltum or other substance used as an insulator, and this gas, mixing with the air of the man-hole, may be easily fired by the heat of an arc or spark subsequently to its production, and cause a violent explosion. The remedy is thorough and continuous ventilation of the spaces in the man-hole and subway. An instance of a storage battery car being wrecked, from a similar cause, is on record. In this case the battery conductors were probably overheated by a short circuit and filled the compartment in which the batteries were with inflammable gases, and the further heating fired the mixture, the result being a violent explosion which greatly damaged the car. Such accidents always involve personal risks, and are to be prevented by simple means properly applied.

But the popular mind is so used to gas explosions that the newspapers have only a few lines to devote to them, while an accident in which an electric shock is obtained, although it has taken place through disregard of some simple precaution, is more than likely to be copiously provided with head lines and harrowing details. I even find one of the journals, whose name states its scientific character, attributing both the Lynn and Boston fires to electric wires. There is on exhibition at Lynn, as a curiosity, the oil stove which caused the fire, and inquiry into the cause of the Boston fire has, so far as I can learn, rather tended to discredit the theory than to confirm it. Notwithstanding these facts, it is true that under faulty conditions of lines or plans, fires may arise, and hitherto have arisen, traceable directly to the heating effects of electric currents. Perhaps if the accidents which happen serve to enforce the fact that the best work, the most thorough provision for emergencies, and careful consideration of details of electric work will be requisite to secure proper safety in the electrical field as in other classes of work, their mission will be fulfilled. Severe and inconsiderate as has been the dealing with the wire question by the authorities in New York city, yet it cannot be denied that the condition of the overhead circuits there had been, in the past few years, going from very bad to much worse. In many cases considerations of safe working would seem to have been neglected in the competition for business. The lines of four or five different companies competing in the same territory might be found, the result of this condition being, without doubt, to enormously increase the risks. There have been hints of the coupling up of dynamos in series, and so increasing the potential of lines already worked at too high pressures in relation to their condition of insulation, and to the placing of the lamps or other work supplied from such lines. Along with this we find the air full of telephone, telegraph and signal wires, of various sorts, none too secure from rusting out or breaking. Many of these latter wires could, no doubt, be easily buried underground, with advantage to the service, but it is certain that to attempt to bury the electric wires in a hasty, ill-considered fashion, merely for the sake of getting rid of overhead lines, would be productive of no good results, either in avoiding risks or bettering the service. The placing underground of very many of the wires now found overhead in our large cities is, in my opinion, a matter which must come in time, but it should be done carefully and gradually, so as to secure the best work. Meanwhile the re-organization of existing wires, the removal of unused wires or redundant wires, as where two systems or circuits in the same territory overlap while serving substantially the same purpose of supply and the use of first-class insulation on the wires would go far to securing safe working and uniformly good service. Besides all these precautions, and outside of them, wherever the conditions are and have been favorable to safe installation of overhead or underground circuits, there are to be found a class of appliances which are called "safety devices," inasmuch as it is their purpose to provide for abnormal conditions and remove risks which, with perfect working and maintenance, are usually absent, but may be brought into existence by accident or unforeseen defects. Such risks may be by outside interference with lines, or by lightning, by falling or poorly constructed signal and other wires upon overhead wires, by unusual wind or sleet storms, by failures of all kinds, as in the working of lamps, switches, etc. It is here that the safety device is found to be useful. Such devices are to the electrical systems what check valves, overflows, traps and safety valves are to hydraulic systems. There is, of course, no room for doubt that if the insulation of all parts of the plant, as dynamos, lines, lamps, etc., were maintained always at its best, and if the mechanical strength of lines, hangers, poles, etc., could be always relied upon, and further, if the effects of lightning induction were never present, there would be but little use for any purely electrical safety appliances, such as those for guarding against leaks and diversions of current. To expect such perfection of conditions is to expect too much. A rigid system of frequent testing can, however, go far to anticipate and to discover the departure from such safe conditions, and enable the disturbing conditions to be removed. Nevertheless, there will always remain opportunity for unskilled or careless handling so altering the condition as to provoke trouble; there will always remain chances of undiscovered defects, chances of interference from outside. The effects of lightning are an important factor during the thunderstorm season. I am driven to conclude, therefore, that safety devices are, and will continue to be, important factors in electric work. The more thoroughly they are adapted to their intended functions, the greater the security, and the more extended their application. That system of distribution will surely survive, which, while involving economy of first cost and maintenance, at the same time secures the greater safety and embodies the greatest flexibility. I assume, of course, that the running economy is practically good in every case.

In the very early days of arc lighting, with a single lamp only on a circuit, the idea of safety from fire or shock did not present itself. When such lamps began to be run in a series of eight or ten, or more, the need of an efficient cut out was felt, so that a defective lamp failing to feed its carbons should not burn with a long arc or flame, and so involve risk of fire, or extinguish the other lights. This need was met in 1876, by Lontin, who used the shunt circuit to actuate a shunting switch around the defective lamp. The Brush cut-out followed, and was a decided improvement on Lontin. Fuller and others early went over the same ground. The film cut-out, or shunting switch, depending on a small thickness of a high resistance insulator, such as oiled paper, to prevent its closure, which paper film is overcome by the difference of potential or pressure between the carbons when a long arc forms, was brought out by the writer, and later, the "vacuum cut-out," a modification which rendered the device self-setting for repeated action if needed. It is scarcely necessary to add that spark-catchers and enclosing globes with wire nettings, were early additions to arc lamps to prevent sparks reaching inflammable material near by, and the globe also in addition served to diffuse the light. Current regulators were additions to arc machines, and acted to prevent undue current, and secure thereby not only safety, but good service. The fact that good service in most cases is assisted by appliances which ensure the safety, or is even dependent on them, is a fact which ought not to be lost sight of in connection with the general subject of electric installation.

The early installations for arc light in and out of buildings, were made with bare wire circuits, and it is a satisfaction to me to recall in these days of forgetfulness of the benefits conferred by electric industries, and exaggeration of the dangers of properly installed plants, a case which occurred in connection with one of the earliest commercial plants of the Thomson-Houston arc lights in 1879. The machine of about eight or nine lights capacity, with bare wire lines, was put up in a large brewery in Philadelphia; two arc lights lighting the stables in which were thirty, or more, valuable horses. One evening a fire started in the hay-lofts in the story above, and where there were no lights of any kind used, and soon the flame and smoke spread to the stable room and menaced the horses. The proprietor happened to think to start up the electric lights at this juncture. Their brilliant rays saved the animals, which were removed without trouble, and the lights were kept burning during the progress of the fire. Its spread was limited by the efficient work of the fire department. The arc lamp globes were at times full of water, but, to the surprise of the firemen, the lights were not extinguished, but assisted them in their efforts very materially.

As the number of arc lights placed in a circuit grew, the necessity for thorough insulation was appreciated; the effort to secure which, for arc lighting lines, has resulted in very great improvements being made in the past few years. So far as electric wires go, the best "safety device" is a perfect insulation. In order that this matter shall not assume the condition of a trial of strength between armor and armor-piercing, as in naval affairs, with a constant growth of both, the advantage always being on the side of armor-piercing or insulation-piercing, I think that efforts to run more than a certain limited number of arc lights in series should be discouraged. Eighty, or one hundred lights, or even more, have been run and could doubtless be run safely under favorable conditions, but I doubt that such conditions can be found in city work, the interfering actions are too numerous, while the maintenance of good conditions would be too expensive. Without such good conditions there would be grave dangers involved.

It has become a practice to use incandescent lamps of low resistance in series on arc light circuits or other constant current lines, and much useful work is so accomplished. Here, again, safety from fire risk depends on certain safety devices, the most important of which is the shunt-forming device, when the carbon lamp conductor breaks. A number of very simple and effective devices are employed for this shunting action. Without such devices the tendency to arcing would be very great. It is advisable also not to rely on any one device alone for this purpose, especially if the lights are used indoors. Here the film cut-outs may supplement the action of a shunting device operated by the heat of an arc set up when the lamp carbon becomes discontinuous. These latter are the fusing cut-outs, twisted wire cut-outs, and others which connect the lamp wires together in the lamp, and so form a complete shunt. Other forms exist, notably the third wire cut-out, acting by diversion of current from the arc to a third or intermediate wire between the lamp conductors.

As in the case of the other devices mentioned, the perfection of operation of one, or a combination of several of these shunting contrivances, conduces not only to uniform service but to absence of risk. Absolute cut-off switches are now in common, if not in universal, use to cut-out loops of series circuits, and in a measure may therefore be regarded as safety devices, but not of an automatic character. Outside of these factors just mentioned, safety in such circuits rests in insulation and maintenance, avoidance of leaks, or crosses, proper placing of wires and lamps, avoidance of partial contacts or partial ruptures of the circuit at joints, binding posts or switches. In series circuits, the main object is to avoid a concentration of, or establishment of, large differences of potential at points in the line where the currents find or can find a path; in low potential, multiple arc systems as used in direct incandescent work, the object is to avoid concentration of current at points where such current cannot find a sufficiently low resistance path. Hence there is required cut-offs for current when excessive in any part of the system. Short circuits of accidental character must be provided against. If the safeguards are not ample, a more potent fire producer than a short-circuited section of an extended multiple arc system, is hard to find. Take out your fuse wires and replace them with copper wires, a practice, instances of which were not difficult to find in times past, and a short-circuit may quickly heat a long line of wire in a building, so as to set fire to the insulation of the wire and surrounding woodwork. The fusible wire cut-out, if properly made and used, is an effective preventative of such risks, though magnetic cut-offs are preferred by some, though more expensive. The magnetic cut-offs, which are simply open-circuiting switches, controlled by magnets in the branch or line so as to open it on excessive current, have the advantages of promptness, avoidance of the scattering about of fused metal, and can be reset without any renewal of material, so differing from the case of a fuse wire. Another risk in such systems is that of creeping of current from main to main over moist surfaces, or partial conductors, in amount insufficient to blow a fuse, but sufficient to convert enough energy into heat to set a fire. Good waterproof insulation of wires avoids this risk if the insulation remains intact. I consider the plan of running the two branch wires, excepting the larger ones of the system, near together or close together, as excellent in avoiding this risk, provided the wires are encased in insulation and covered in, or run in a tube. In case of a leak from main to main, the more quickly the fuses blow the better, and the proximity of the wires assists this speedy action, while between the wires there is not at any time enough combustible matter to set afire by the short-circuit. Enclosure in a tube effectually shuts off possibility of flame reaching combustible matter before the fuse blows. This does not apply to the heavier mains, capable of carrying thousands of amperes, so well as it does to the smaller branches. I am glad to note here that the tube or conduit system appears to be well worked out for inside wiring by the Interior Electrical Conduit Co.

Another thing to be avoided in extended systems of multiple arc work is grounding or leakage to ground of current over resisting surfaces or materials. The tube system is useful here as well, and the placing of two wires at difference of potential, near together, assists somewhat, but does not entirely remove liability of grounding. Testing for grounds in the system, taken in sections, is the proper procedure, although this does not provide against all suddenly formed leaks. It may be argued that in this case two grounds are necessary to cause a leak, one on each side of the system, and this is true, but in very extended systems of overhead work, more or less general leak exists which may provide sufficient current to feed, as it were, a local leak to ground from either main.

Let us now deal with what is called the alternating, or induction system of supply, in which the local, or house mains, are separate from the primary mains, and of much lower potential. For lighting purposes the system is very flexible, and enables distance to be overcome. The secondary circuit is, or should be, entirely out of connection with the primary mains of high potential, and the potential differences of the secondary circuit may be so low as to be incapable of giving a severe shock under the conditions of use, and to be almost incapable of setting fire, on account of the absence of arc forming tendencies. This is, indeed, an important factor in alternating current work, and conduces to the perfect working of switches and cut-outs, and the prevention of diversion to ground. Good work is all that is needed in this case to abolish all risks, if we leave out the main high potential current. The local line is unaffected by leaks or grounds at other parts of the system, and is, therefore, in this respect, in a better condition than is found with the consumer's lines in any direct system of supply. On the other hand, all the cases in which persons have received a shock from an alternating current of 1,000 volts or upwards, without being killed, are fortunate accidents, for there cannot be the slightest doubt that such current can and will kill under conditions favorable to its passage through the body. There are many cases of severe shocks having been obtained from such currents without permanent injury. On the other hand, there is a sufficient number of fatalities on record to sustain the position taken. The risks with higher than 1,000 volts alternating current are, of course, greater. It must not be forgotten, in this connection, that the actual potential differences in an alternating current of 1,000 volts are higher than that figure, and may be, at every wave, upwards of twice as much. This confers on such currents an actual and measurable striking distance between the two mains. As with arc lighting lines, the main or primary wires, if overhead, requires to be kept thoroughly insulated and free from leaks to ground. The covering for the wire should be capable of resisting moisture, and the wire used be strong enough to prevent any possible breakage. If the primary wires break and come down, they are still kept charged from the dynamo, which is not always the case with arc light lines. If, however, the insulation is strong and perfectly good, the risk to life is small in such case. There is one fact I wish to impress, however, and it is, that, with a parfectly insulated set of alternating primary mains feeding transformers, there still remains the static capacity of the line or cables and transformers, and this may be of an amount sufficient, if a person is grounded and touching the primary line, uninsulated, to give a severe if not a fatal shock. This inductive shock or discharge is, of course, far more pronounced with ordinary underground conductors than with aerial lines, and increases with the size and number of transformers and the extent of the line. It also increases as the voltage of the primary line is increased. Hence, it is quite important that no leak or connection exist between the primary line and a secondary in such system, or otherwise there may be a transfer of potentials of the primary line to the secondary so as to involve risk of shock to the consumer, or risk of fire from leaks to ground indoors. It will not do to say that such connections do not often form, for they may form from defects in construction, from moisture, and particularly from lightning discharges. A person standing on a damp floor, leaning on a steam radiator, touching a gas pipe grounded, or in other ways, may, if he handles or touches the secondary line at any part of it, be in peril of severe, if not fatal shock. What was without this condition a most harmless local line, becomes most dangerous.

The writer early recognized this danger, and felt that unless it was provided for, the induction system was not advisable for general use. As a consequence, the expedients of grounding the secondary, or of surrounding the secondary by a grounded sheath, or of cutting off absolutely by automatic means the local line when connected with the main line, or of automatic grounding of the secondary by insulating films or spaces which are punctured or overcome by the potential of the primary when connected with the secondary, were devised as safety devices. The grounding of the secondary is the most simple and effective if good grounds be made. It must, however, be done with certain precautions to insure the best results.

The second expedient of a grounded metallic sheath between the primary and secondary is persistently called "Kent's sheath" when alluded to by our English cousins, despite the fact that it is American in its origin. It is effective as a protector, as it carries to ground any discharge leaving the primary before it reaches the secondary. The sheath is easily made by placing a somewhat open wrapping around either the primary coil or the secondary coil of the transformer made of flat metallic ribbon or insulated wire, the ends of which are grounded when in use. The course taken by the wrapping is around the wire of the coils at right angles to its direction of winding. The automatic absolute cutting off of the connection between the transformer coils is also effective, and has undergone several modifications in other hands. The last protective device mentioned above leaves the secondary insulated from the ground until a contact or leak from the primary takes place, when an automatic ground is made. One of the forms consists in the interposition between the ground and the secondary coil or line of a film cut-out, or thin paper film between two metal buttons pressed together, one button connected with the ground, the other with the transformer secondary. This device is very effective in securing a safety ground connection of the secondary when the primary leaks to it. A well constructed transformer properly installed will not, except by accident, lose its insulation between primary and secondary, and such insulation should always be many times that otherwise requisite, so as to have a margin of safety; but the safety device is none the less a necessity in its use.

I consider that a properly arranged double wire cable, well insulated, constituting the primary line, laid in ventilated pipes underground, transformers connected therewith, also enclosed in a grounded metal case, as in the cellar of a building, a secondary line of low potential, grounded, or provided with safety devices as mentioned, embodies as safe a system of incandescent electric light distribution as can be devised, both as to risk to life and danger of fire. It ensures complete safety to all the consumers, and to each one individually. It enables long-distance work to be undertaken, and allows low voltage lamps to be used with their increased economy. The risks are confined to the electric station and the primary lines, which should be handled by men who know their business. The non-commutation of the current at the generators is another advantage, of course. The disturbing influences, which in the best organized plant may be introduced by lightning, are serious and sometimes destructive. It is not that the lines are *struck* by lightning that causes the trouble, but the mere *inductive* current or discharge from a flash of lightning is quite sufficient. It puts upon the line potentials of many thousands of volts and tends to break down insulation everywhere. Lightning arresters are, therefore, important safety devices in more senses than one. They save the machines in the station and the apparatus outside. In the alternating system they save from puncture the insulation between primary and secondary coils of transformers and between the turns of the primary coil itself. Every plant, then, should, if subject to lightning induction, be provided with efficient lightning arresters or dischargers.

A discussion of this general subject, however brief and necessarily restricted in scope, would be very incomplete without allusion to the subject of contact with telephone or telegraph wires with electric light conductors. Underground and in conduits such contacts could not easily occur, though leak might readily take place between lighting conductors and other wires. In any case, there is a risk of such wires carrying current into buildings or to positions bringing about shocks to persons, thus involving risk of fire or danger to life, or both. As a consequence a set of safety devices have been brought out under various names whose purpose is to cut off dangerous currents when they reach or traverse lines, such as those of the telephone or telegraph. It is my opinion that in cities the provision of approved devices of this kind should be compulsory. Most of those which I have seen are not well enough designed or made to be perfectly relied upon, but are much better than nothing and may possibly suffice. Such apparatus, however, should be made so as to be perfectly reliable and undergo a regular inspection. Mere fuses, even if made long, are not enough. There should be placed in every circuit liable to contact with lighting or such like conductors, and at a place in the circuit where it enters a building, a protective device which, to be complete, should shunt or absolutely cut off the section of wire indoors, or ground the same in case of abnormal current on the wire or abnormal potential.

There is much more to be said on this subject, and I am conscious of only having touched upon certain important matters in this paper. If I have succeeded in pointing the way to better conditions in any case, I shall be more than satisfied.

To sum up briefly, safety in outside work means care in placing, maintaining, and insulating conductors, whether used overhead or below ground. This means the employment of only good linemen, and not men who are ready to incur risks through a reckless disregard of conditions of failure to comprehend their importance. Men who have done telephone or telegraph line work are not necessarily prepared to undertake electric light and such other work with the best success. Safety in inside work means, primarily if admissible, separation of the inside circuit absolutely from the general supply mains, and in any case it means that good, careful workmanship is requisite, and that the employment of safety devices, amply sufficient to do the work required of them in case of accident, is imperative.

Safety from current entering buildings upon telephone, telegraph and other wires, means first, a more systematic placing of such lines apart from electric mains, whether above ground or below, guard wires and insulated wire for such lines, stronger wire, especially for telephones, and the employment of safety devices in case of accidental leaks or crosses occurring with electric mains, of either low or high potentials, and a periodical inspection by proper officers.

CONSTRUCTION OF CENTRAL STATIONS.

BY C. J. H. WOODBURY.

[Abstract.]

In co-operation with a committee of the National Electric Light Association, several years ago, it was necessary for me to examine the construction and surroundings of a large number of lighting stations. We found a diversity in their characteristics wholly inconsistent with their similarity of purpose.

The present paper is to be regarded as the opening of a discussion, hardly more, in order to bring the subject into a debatable form.

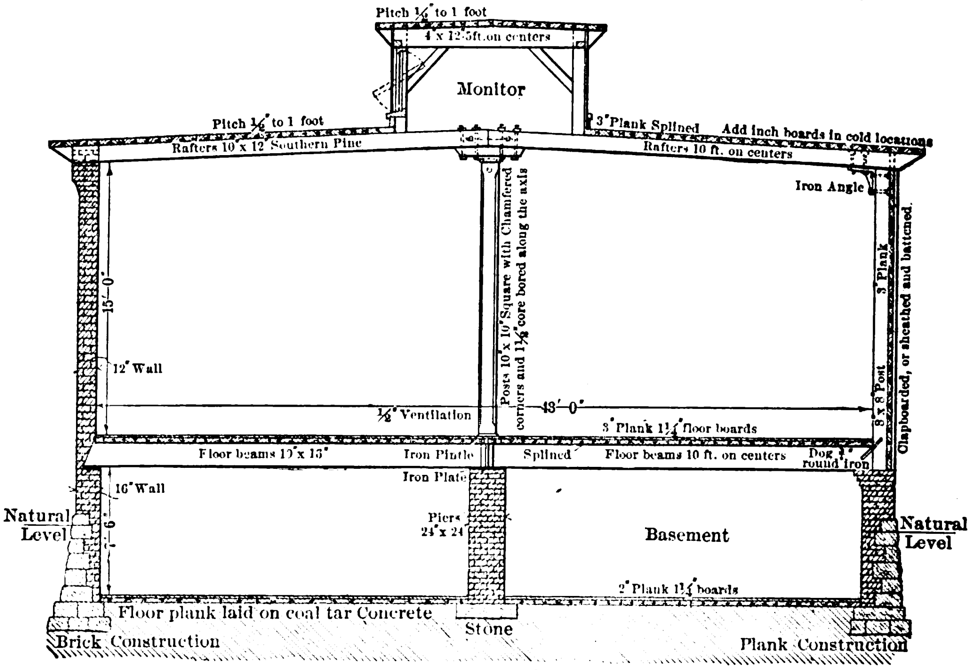
Many electric lighting stations in large cities have been built under easy financial conditions, where it was feasible to adopt suggestions for convenience, strength and safety. Notable examples of such stations have been presented before this Association, or illustrated in the electrical journals. The opportunities for large stations have thus far been so few, and the governing conditions so diverse, that the problem requires in each instance an independent treatment, and is, therefore, unsuited for a general paper on the subject.

The larger part of the electric light stations are of moderate size, and were constructed under conditions of limited resources which often compelled parsimony in the reduction of first cost, and did not permit the exercise of that judicious economy which yields the greatest return on investments.

A most important element in the arrangements of a central station should be the guarantee of continuous operation. Many of the stations are in close proximity to other buildings of a miscellaneous character, and are built with hollow frame walls and thin roof, forming a structure which is hot in summer, cold in winter, and combustible all the year 'round—which disadvantages diminish dividends. The location to be desired for a station is, first, away from other buildings, and, therefore, free from a fire hazard due to surrounding exposure. It is important that the engines should be provided with an independent condenser, but it is not necessary that the station should be near a water course. A reservoir of suitable capacity, will furnish a supply for condensers, which can be used over and over; the condensed steam and hot water entering one side of the reservoir, and the supply for the condenser being taken from the other.

In its general arrangements, a central station may be regarded as an engine room, and if well adapted to engines and the delivery of power there cannot be much difficulty in providing accommodations for dynamos. The type of building suggested for central stations in small cities, is the one-story slow burning construction, with flat roof, lighted by a longitudinal monitor, one end of which extends high enough to form a wire tower. It is not claimed that there is anything original in this design beyond a few minor modifications, for it is well known that beginning with one-story machine shops over 25 years ago, foundries, textile and paper mills, on the same general idea of construction have been widely introduced, wherever the cost of land was low enough to permit the erection of a one-story structure without raising the whole cost of the floor area, including the expense of land, to a price exceeding that of a high building.

Franklin once said that next to a good foundation, a good roof was the most important part of a house. The question of roof will next be considered.



The most convenient width for stations using an engine to every pair of dynamos is 43 to 45 feet, and the length of the station is in proportion to its capacity. The roof should be of three-inch plank, each 20 feet in length, grooved and splined with hard wood splines one-half by one and a half inches, and laid on roof timbers breaking joints every three feet. In colder parts of the country, it is good economy to lay a course of inch boards upon the plank, with roofing felt between. Pine is preferable to other lumber for roofing, as it does not warp much. The roof covering may be of any material for covering flat roofs, but its value will depend upon the quality of the material and the character of the work. If these methods are followed, such a roof can be relied upon not to give trouble by condensation of moisture in cold weather; but care must be taken not to drive nails up into the plank, because being good conductors of heat, the heads would be cool and moisture collect on them.

Along the middle of the roof, a monitor 10 feet wide, extending to 20 feet from the ends, will afford light and ventilation, while an extension of this monitor at one end to a suitable height will form a most convenient wire tower, if the monitor, in connection with an outrigger, should not be high enough for the purpose. The roof timbers should be of southern pine, 10 by 12 inches, and laid 10 feet on centres. They should project 18 inches beyond the walls, and the ends be cut to form brackets supporting the overhanging roof and forming a solid cornice. At the ridge, the two beams should be secured together by a junction bolt, and supported by column and bolster.

The walls of the station may be built of brick or of wood. If of the former, a 12 inch wall will answer; but if of wood, each roof timber should be supported on an eight by eight inch timber reaching to the sill, and secured to the roof timber by an iron brace, and to the floor timber by iron dogs.

If the building is to be used for low tension currents, the best floor would be made by laying coal tar concrete on a foundation of broken stone or cinder, and then laying three-inch plank upon the concrete, and covering this plank with one and a quarter inch hard wood plank laid across the bottom plank and blind-nailed to it. Such a floor would sustain any weight liable to be placed upon it.

If the high tension currents impose conditions requiring a higher insulation of the floor, such as can be obtained only by an air space underneath, then it may be necessary to lay a mill floor by placing the two thicknesses of planks on beams in a manner similar to that described for the roof. If the dynamos were placed on independent foundations, this floor would be strong enough, but if it should be required to sustain very heavy loads, there should be a line of piers supporting the beams under these loads. The lower portion could be made into a supply room; or otherwise, the front of the building could be divided by a light sheathing partition into a supply room and an office.

The building should be heated by two coils of three lines of 1¼ inch pipe, each hung about three feet below the roof timbers, the proportion of piping, using exhaust steam, being about one foot of 1¼ inch pipe to every 70 cubic feet of space. Two coils are suggested, because the side occupied by the steam engines would rarely need any heat from the pipes.

The roof timbers afford easy means of securing a trolley track for making changes and moving apparatus or parts of the engines.

The protection against fire consists principally in keeping the establishment in a clean and orderly condition, the use of good lubricating oil, and careful attention to the bearings; numerous pails kept filled with water, and hose connected to hydrants ready for instant use, will serve to put out incipient fire.

If the boiler house is placed at one corner of the station, the latter can be extended by increasing its length; but if the boiler house is placed at the end of the station, the division wall should be made of brick and extend through the roof, entirely cutting off all wood communication between the station and the boiler house.

The wires could be run from the dynamos diagonally upward to the roof timbers, clearing the trolley track, and thence under the monitor from beam to beam to the switch-board on the floor under the end of the monitor forming the wire tower. This switch-board would be at the end of the unavailable floor space used for belts, and away from the walls, where combustible material is likely to be placed. It is important that the switch-board should be made of soapstone or other incombustible material.

It is submitted that a station built in accordance with these general suggestions would embody the merits of convenience in operation, slight need of repairs, and, whether built with brick or plank walls, would possess a resistance to fire which would reduce the fire hazard to a nominal amount; and although not so cheap in its first cost as might be made by using a lighter construction, yet, as a whole, it would conform to the strictest conditions of economy in a building to be used for a central electric lighting or power station.

NINE YEARS WITH THE ARC LAMP.

BY M. D. LAW.

[Abstract.]

MANY irregularities in arc lamps can be remedied by a judicious study of their actions. To find the special trouble a careful record should be kept of each and every lamp. Give each lamp its individual number, firmly attached and never removed; then in a numbered book a page for each lamp, a record may be kept of all lamps, where they are, when changed, with the kind and amount of repairs. If a lamp is continually being changed for the same cause, there is some one thing that is radically wrong; this should be found and rectified. For instance, a lamp works perfectly on the test rack, but, after being in use a short time, has to be changed for dropping. If from the records this is found to be its general complaint, look for the trouble—if a Brush lamp, in the winding—that is, in the resistance of wire on the magnets. The resistance of the magnets should be kept as near as possible to 85 ohms; never allow more than three ohms variation from that amount.

If the following rules are strictly adhered to in putting together a Brush lamp, it will be found to burn correctly with but little adjusting.

See that the device carrying the lower carbon holder is parallel with the side rods; also that the screws, etc., at its base work freely and allow it sufficient lateral motion in all directions to affect adjustment.

See that the lower carbon holder is in line with its support, or the carbons will not centre.

See that the brass tube carrying the upper carbon holder is straight, smooth, and free from small or flat places, and that it moves freely in its bushings, which should not be too loose, as this will allow the carbon too much lateral motion, making it liable to slip past or wedge.

See that the upper carbon holder is in line with the rod.

This last adjustment is very important, and is made by clamping a steel rod of the same size as the carbons to be used in the holder, and revolving it between the thumb and the finger, noting whether the lower end of the rod revolves on its own axis or "wabbles," in the latter case, push the holder up to the lamp box, and, by means of the testing rod, bend it slightly in the proper direction to correct the error, then see that the carbon holder has not become loosened; test again, repeating the process until the desired adjustment is reached.

Examine the lifting washers which surround the carbon rod, see that the hole is counter-sunk on each side, so as to make the available thickness of the washer where it touches the rod but little more than a sixteenth of an inch. See that the hole in the washer is of such a size that one side of the washer may be raised one-sixteenth of an inch from the horizontal floor on which it rests, before it clamps and commences to lift the rod. See that the holes in the washer and bushings are nicely polished. The lifting finger, designed to lift the washer, should move freely in its guide and get a good hold under the edge of the washer, and allow the latter to rest flat on the floor under it when the finger is down. In the case of double lamps, the lifting finger should be so adjusted as to lift the second rod one-sixteenth of an inch ahead of the first.

See that the movable brass parts connecting the lifting finger with the movable magnet cores work freely at their joints, so that no binding of the parts may be possible.

See that all the parts of the dash-pot are free and do not bind. See that the armature of the cut-out moves freely on its pivot.

In the Thomson-Houston lamp the clutch should be of german silver or some more durable metal than brass, as the bearing point of the clutch against the rod is so small that it very soon wears and thus throws the lamp out of adjustment. When one of these lamps is found dropping, it can very often be remedied by lowering the adjusting nut (No. 692) a trifle, when the lamp will again burn correctly.

Another improvement in this lamp is, increasing the thickness of the insulations, which are too small in nearly every case; especially is this so with those under the binding hooks at the top of the lamp box, which I find work excellently well made of porcelain.

The general causes of the Thomson-Houston lamps dropping are numerous; but if all the working points move freely and without lost motion, it will reduce the number to the few following points: Badly worn spots in the carbon rods, this is a common fault of all arc lamps. The clutch or lifting spring may have lost their temper, these should be made of bright instead of black steel. Clutch arm bent. Clutch or carbon rod bushings may become worn. The adjustment nut (No. 692) may be too high or too low, the clutch or tension spring may be too tight. Crooked frames, bent rods or rods striking the chimney, tight bushings, fine wire broken, dirty rods, brush in the bushing may be too tight or become corroded or burned, and the magnetizing of the armature before spoken of will cause the lamp to flame and drop.

With the United States or Weston lamp the principal cause of trouble is the tripping from first to second set, and when this happens so that the second set burns first, it generally means a new set of contact springs and new magnets if the lamp burns entirely out of carbons. Some of the causes for tripping are: rod sticks or wants new contact brush, lever hook loose, rod scrapes chimney on first set or too much hook on first set, adjusting screw on long hook set too high, lost motion in rocker shaft. Causes of long arc are, platinum collar dirty or worn out, trip lever sticking or too loose, carbons not burning in proper proportion, burning holder before the carbon rod is down far enough to make contact with trip, small hook dirty, rod crooked near the top, weak magnet, fine wire burnt, clutch holder or armature sticks, rod a little thick at the top and brush too tight. Causes for dropping out are: weak magnet either fine or coarse, lost motion in rocker, stiff clutch, too much clutch, not enough clutch, slight nigger in coarse wire, plunger too stiff or too loose, plunger bent, broken or crooked plunger rod, bad carbons, which may on starting become soldered together and cannot lift.

The globe holder or carbon holder of arc lamps is a very much neglected part—that is, the insulations are not made heavy enough, but that the carbon dust or copper droppings falling over the insulations will give such leak that a person standing on the ground and touching the bottom of the lamp may receive a very bad shock; this insulation should be made heavy and so placed that the carbon dust may not fall on it, for it is sometimes impossible to hang lamps under awnings so high that a person passing under may not touch them with an umbrella or other conductor. No part of the lamp outside of the globe should be allowed to have current in it. Arc lamps should be suspended by some perfect insulator, the regular porcelain insulator and hook being the best in our experience; this is a very important point and is often neglected. Dirt must not be allowed to accumulate on any part of the lamp; rods, switches, bases and globes should be kept well cleaned, and all binding screws kept tight, the rods should be kept thoroughly well wiped every day with a clean cloth or waste; never allow crocus or emery to be used, they badly wear the rods in the middle.

Our longest record for any one lamp in a constant street service is three years and nine months without any adjustment other than the ordinary cleaning by the trimmer.

In order to get a good lamp record, no lamp should leave the test rack until it is perfect in all parts.

The most vexatious part of the arc lamp is the globe, it swells the item of expense in spite of the utmost care, besides being a great source of complaint. I have found that it pays to put wire nets (which should be made of copper) on all globes, even for street lighting; this prevents pieces from falling out even after they are badly cracked, and if the globe entirely gives way, the net will prevent its falling on some one's head. Undue heat after the carbon has burned close to the holder, is one of the greatest causes of broken globes. This can be partially overcome by leaving the globe about one and one-half inches from the carbon holder.

A serious point in station management is the pay-roll. Two men more than are necessary will cost nearly as much as a ton of coal per day, and thirty tons of coal per month would be quite a saving. While keeping the number of men as low as possible, none but first-class men should be employed. Especially must trimmers attend to their duty well, as the quality of their work controls the amount of rebates to be allowed disgruntled customers during the month. Another important man in this respect is the dynamo man. He should give the dynamos the most assiduous attention, that the strength of the current may be kept constant, while flashings and interruptions may be reduced to a minimum; for no matter how well every other department of a station is carried on, if the current is allowed to vary from the standard, complaints will follow, and they are expensive.

There is nothing that angers a user of electric lights so much as to have them flash; it may be only one or two seconds that they are out, but it always seems like a much longer time, especially if in a crowded hall. Rather have the record for continuity of lights so good that the gas fixtures may even be removed; this can only be gained by close attention to the machines, wires and lamps.

I call to mind one place that we have lighted continuously, without any other method of illumination than arc lamps, for over eight years, and during that time the lights have never been out during lighting hours.

The waste in the use of carbons is a very important feature. These should be dealt out and every stump returned; the amount saved in laying by the four and five inch stumps to be used in the summer months will make a saving of at least 10,000 carbons per year for a 1,000 light station.

At the time I first started dealing out carbons and bringing in stumps, I saved on an average over $30 per month, and then only trimming about 400 lamps per day.

An arc light wire should never be concealed.

The use of soft rubber tubing for passing through floors, ceilings, walls, etc., should never be allowed, the only suitable material for such work is hard-rubber tubing.

While I am a great believer in the use of the best quality of insulation for line construction, yet it is not best to depend entirely on such insulation for safety. Put up the best wire there is, and then apply a rigid system of inspection and tests—not by that abomination of tests, the magneto bell. Not only should the tests be made on dead lines, but they should be made at least once in two hours on all live wires, and when grounds or bad leaks are discovered, they should be immediately cleared, by that means forestalling the second ground, which is the element of danger. I have repeatedly had lines that would test clear at the time of putting on circuits; but two hours after, solid grounds have been discovered, located, and found to be wires broken down, hanging over the electric light wires and reaching down to the sidewalk, where they are a source of danger to every passer by; besides every boy that passes must feel of it to see if there is any electricity in it. My orders are to clear grounds at once, dropping all other work that is not absolutely necessary.

In Philadelphia we receive great help from the electrical bureau of the city, through their prompt reports of all wires discovered in contact with ours.

All lines should be cut by one man, who is especially instructed and detailed for that work. Teach every employé never to depend on any insulation, but to treat all wires and lamps as if they were charged with an electric light current; dangers to employés will thus be reduced to a minimum.

HOW OUR PATHS MAY BE MADE PATHS OF PEACE.

BY H. W. POPE.

[Abstract.]

PREVIOUS to the introduction of the telephone, the standard of out-door or pole line construction may be said to have been that established by the Western Union Telegraph Co. The lines were never of a superior character, nor comparable with those in European countries, and it was not until after thorough inspection and exhaustive tests were made by a prominent English electrician, employed for the purpose, that extensive alterations and improvements were made.

The construction of an excellent line on the route of the Pennsylvania Railroad, between Jersey City and Philadelphia, by the American Union Telegraph Co., marked a new era in line construction, but the standard thus established was never closely followed by telegraph builders generally.

To those of us who have been identified with electrical interests for the last quarter of a century, there seems to have been no notable improvement in telegraph and telephone line construction, except as shown in the recent interstate lines of the American Telephone & Telegraph Co. The introduction of the telephone brought into the electrical field a very large class of workers devoid of electrical knowledge or experience. To this class, the methods employed and the standard of construction prevalent, were superior to the necessity and requirements of the telephone. This opinion and the lack of sufficient capital to exploit properly the telephone business was primarily the cause of the introduction of poor material and workmanship, as well as the small wire and insulators, together with porcelain knobs and cheap insulation.

With the experience of our predecessors in the electrical field, and with the knowledge of the character of the current we were handling, it would seem as if a superior character of construction and insulation would have been deemed imperative for electric light lines; yet, with the exception, perhaps, of conductivity, everything has been inferior to that previously used by corporations employing harmless voltage. That such was the case is due somewhat to causes similar to those prevailing in the introduction of the telephone—but the use of cheap insulation, what is popularly and properly known as "undertakers'" wire—was due wholly to the ignorance and stupidity of underwriters' officials, to whom many of us protested repeatedly against its use.

The accumulation of poles, the inferior character of the materials used, and the utter disregard of public considerations or the character and beauty of the surroundings, gradually moulded public opinion against poles and wires in general, and electric lighting in particular.

The desire of electrical manufacturers to crush their competitors, distressing accidents, and the publication throughout the land of magnified accounts of the dangers of electricity, depreciated our property, and retarded the progress of electric lighting and electric traction to a great degree. To this condition of things we must now devote our attention—adverse legislation is cropping out in nearly every state in the Union, tending to regulate voltage—to bury the wires, and to accomplish other reforms. In view of this, it should be the aim of electric lighting corporations to so reform existing methods of construction as to show a decent regard for public opinion as to safety and the appearance of structures. By a sincere effort in this respect, beneficial improvements can be introduced without necessitating large expenditures, and the clamor for the removal of overhead wires reduced to a minimum. Where there happens to be an unnecessary aggregation of poles, endeavor to perfect an arrangement whereby poles may be occupied in unison, and many poles can be removed. Such a course will reduce your maintenance expenses, and create for you favorable public opinion. In the erection of poles, considerable attention should be devoted to their design and proportions, and the character of finish, to the end that the structure may be pleasing to the eye. The question of expense, as compared with common poles, should not be allowed to deter you from the ultimate purpose of replacing your entire line, especially in cities or towns where the burial of wires would be a financial impossibility.

To those familiar with the recent excellent structures of the Long-Distance Telephone Co., or those of some of the electric railways, the manner of improving upon the present methods of construction will readily suggest itself. While it is not advisable to use iron poles, combination of wood and iron can be used to advantage in many instances. It will be frequently discovered upon investigation, that lines of poles erected in the streets in front of buildings can be removed to an alley or street in the rear, or run over private rights of way by the payment of a nominal consideration. Provide every pole with iron steps; paint the poles as thoroughly as you would a house; and select colors that will not make your poles conspicuous.

In so far as a neat, well-designed and substantial brick station reduces your rate of insurance, gives character and substantiability to your investment, so will the improvements suggested—however small and insignificant at first—if properly carried out, win for you favorable consideration and fair treatment, enhance the value of your property, and tend to postpone indefinitely the removal of overhead wires.

It should be the aim and policy of all electrical corporations constantly to improve the condition of poles and lines—giving as much attention to their strength and beauty as to their perfection electrically. The assumption that such a course is unwise, because of the theory that sooner or later all wires must be buried, is wrong, because it is questionable whether such an extreme will be reached, especially in cities and towns of small population. Every day that you delay these improvements you encourage adverse criticism and hasten adverse legislation, state and municipal.

DEVELOPMENT OF GENERATING STATIONS FOR INCANDESCENT LIGHT AND POWER.

BY C. J. FIELD.

I DESIRE to present a brief review of the present and near future of central power plants in the larger cities, taking as an illustration one of recent type, describing its general arrangement, then proceeding to the consideration of its initial cost, earning capacity, output, operating expenses and economy, and in conclusion, trying to indicate the immediate future development in this class of work.

The immediate points to be considered in the designing of central power plant for a large city are many, and they should receive careful survey before any work is proceeded with. We will briefly summarize them as follows :—

First. Recognition of the importance of safety and reliability in operation.

Second. Obtaining the true economy of output under all conditions.

Third. Installing of plant in a building entirely suited to the working of same, and as far as human ingenuity can provide proof against destruction.

Fourth. Adaptability to proper and economical working of the plant.

Fifth. Division of the generating power into the proper number of units for the safe and reliable operation of the plant.

Sixth. Flexibility of system, that is, adaptation to furnishing current for light, power and other sources of revenue, the obtaining of the largest return per dollar invested, and not carrying to excess for the mere sake of engineering by any part of the plant for the obtaining of proper results therefrom.

Seventh. Not installing the plant for mushroom growth, but laying it out for comprehensive business, thereby securing, at as early a date as possible the entire confidence of the invested capital.

A careful consideration of these points will prevent trouble later on. Much of the trouble of stations at the present time, in their standing with the community, is due to neglect of this point, and the majority of their failures as well. We must recognize the fact that the public, to a certain extent, have become prejudiced, somewhat unjustly, but this is all the more reason for better and more conservative management, and good construction. No more inviting field is offered for either investing capital or good engineering than central station for lighting, power and railway work.

I propose to take as a representative type, showing the present development and first-class work, the station of the Edison Electric Illuminating Co., of Brooklyn, completed last fall and now in successful operation.

In the arrangement of this plant there was somewhat of a departure from previous general practice, the company trying to secure the benefit of past experience in the larger stations of this class, both in the kind of arrangement and of apparatus used, trying to secure at as economical a cost as possible, the best plant. As will be seen by the longitudinal section through the building, the general arrangement is as follows :—

The boilers and engines are located on the first floor, the engines being on the front half and the boilers at the rear, thereby bringing everything on this part directly under the eye of the chief engineer, making it much better than where the boilers are located two or three stories up; this was obtained by spreading out a little more on the ground. The boilers are Babcock & Wilcox's largest type of sectional water tube boilers. The engines are 300 h. p, compound, horizontal, automatic engines, manufactured by the Ball Engine Co. Each engine is directly belted to two generators. The plan of the engine and boiler room floor will also show in more detail the general arrangement here used, and, I think, needs no further explanation.

Ascending to the second floor, we reach the electrical part of the plant. Here are located in the front part of the building, directly over the engine room, twenty-four dynamos, each with a capacity of 750 amperes and 140 volts. Each dynamo weighs about eight tons.. Overhead traveling cranes are installed here and in the engine room for ready and quick handling of all apparatus. Through the centre of the dynamo room is located the electrical gallery. From here are controlled the workings of all the dynamos and other apparatus, also all outside lines; everything in connection with handling, generation and furnishing of current, is directly under the eye of one man in this gallery, and from which he has a general view of the dynamo room floor and the workings of the dynamo, a second man being on the floor to see to the bearings and brushes. From this gallery run all the feeders, which connect into the net-work of mains, covering over an area of about one and one-half miles square. The ampere meters are located on each feeder, so as to show the load in each part of the district. This plant maintains its distribution and regulation thereof by balancing within itself. No feeder equalizers are here used for feeder regulation ; the uniting and tying up of the system together with the use of the auxiliary bus affects this regulation. All circuits of this plant are underground, there being about twenty-five miles of underground conductors. These have given perfect satisfaction and reliability in their workings, maintaining to-day an insulation on the system as a whole of over half a megohm.

On the rear of the second floor are located the coal storage, water tanks and feed water heater. On the top floor we have the offices, supply rooms and workshops of the company. Returning down stairs again, we find in the basement, ash pits, smoke flues, pump room, two large coal storage vaults, giving a total capacity for storage of over 1,000 tons, air blast for force draft, and other details in connection with the steam plant.

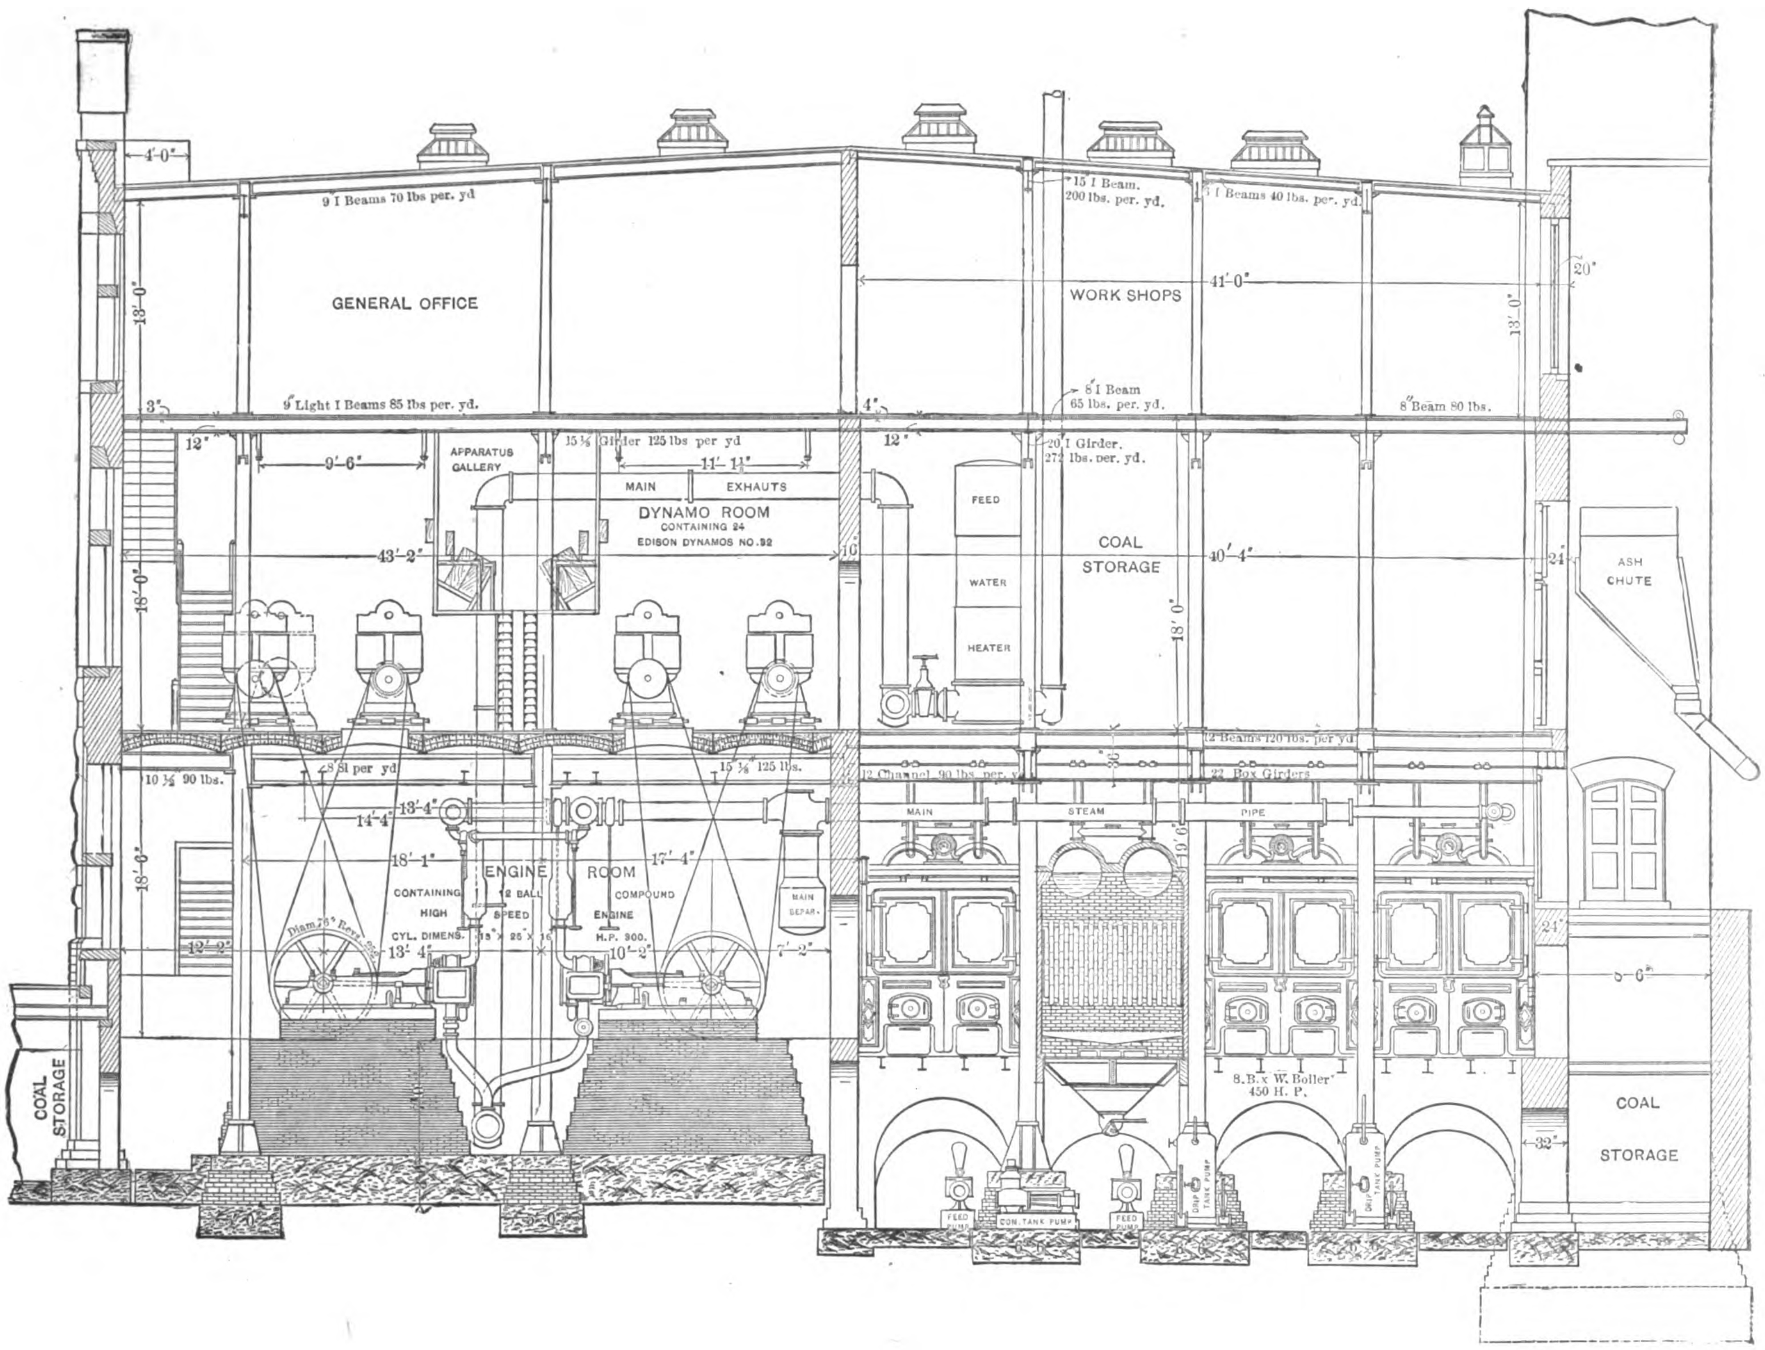
We have, therefore, here, in a building 75 x 100 feet, apparatus and all departments complete for the generation and supply of current of 40,000 lights, or the equivalent in light and power, and so arranged as to secure, as far as can be foreseen, continuous working of the plant and entire reliability in the supply of current. I give you now, in round figures, the cost of this plant as shown by the construction accounts and estimates :—

Station building, complete, including all fittings, foundations, stacks, furniture, etc.	$100,000
Real estate	36,000
Steam plant, including engines, boilers, pumps, heaters, piping, bells, etc.	50,000
Electrical plant, including dynamos and all electrical apparatus, as switches, etc.	40,000
Underground system, material	115,000
Excavation and labor installing same	35,000
General, including lamps, meters, tools, instruments, engineering and architectural expenses, wiring, services and office furniture	50,000
Total	$426,000

This includes the entire cost for the plant as it stands to-day, which as far as the building is concerned, is complete for the entire capacity. At present there is installed generating capacity of boilers, engines and dynamos, for one third (⅓) of the final output of the plant. The subsidiary electrical apparatus is complete for the entire output, with a very few additions in the way of a few switches, etc. The underground lines have a capacity for 20,000 lights. The work necessary to complete the plant for its entire capacity would cost about $200,000 additional.

For this amount there has been obtained here a plant, which is considered equal, if not superior, to any of this class, and at a cost of twenty to thirty per cent. less than has been expended for similar ones.

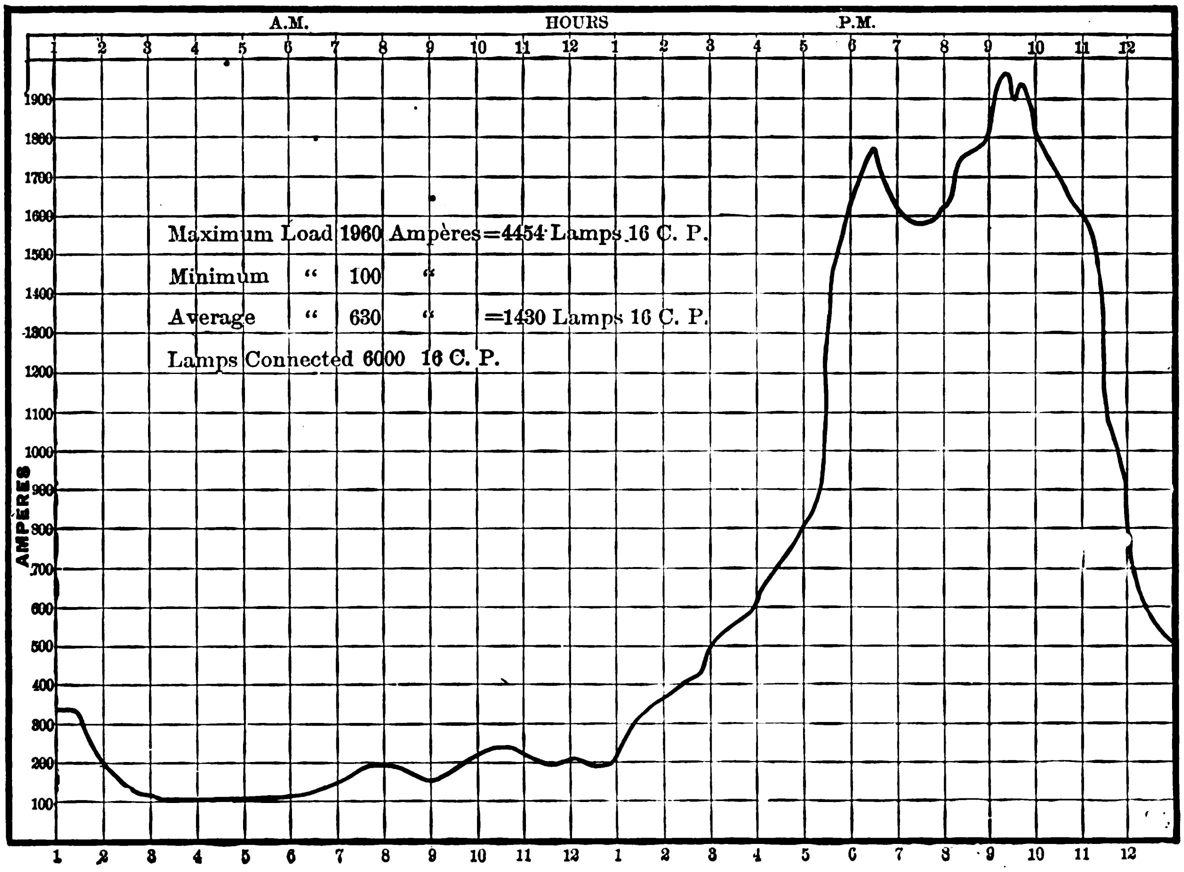
The next consideration is the operating expenses. To place the company on an earning basis we have to secure to start with, a certain number of lights or an equivalent in lights and power, to clear the necessary general and operating expenses, which will exist regardless of the smallness of the load; in other words, we must have for such a plant not less than 5,000 lights with an average income of $8 per light per year to clear the general incidental and operating expenses. This figure we may consider as our unit of operating capacity. From this we can figure the increased earnings and profits for the larger number of lights connected. There exists, practically, a constant ratio of variable and fixed operating expenses. By variable expenses we mean those obtained on a variation in load and increase of business; this includes coal, oil, lamp renewals and small increase from time to time in the amount of labor employed. The fixed expenses include those items which remain practically constant under varying conditions of income. A careful analysis of all the items covered in these expenses in such a station as this one, gives the following result : That the fixed expenses are seventy-five per cent. of the whole, and the variable twenty-five per



LONGITUDINAL SECTION OF BROOKLYN EDISON STATION.

cent. approximately, or in language which may appeal more directly to you, if we double our income or business, we only increase our expenses 25 per cent. This shows that a station's possibilities and profit lie in increasing this business from the unit point.

We have illustrated a load diagram taken from this station, which gives you a fair idea of the changes and variations. The maximum number of lights lighted at any time in proportion to the number connected is very good for such work and shows a good class of business. The load diagram through the day, however, shows a new station on a clear day with a small number of lights lighted, and power work only just commencing. It is this power work that wants attention and the securing of which means the bringing up of this average load during the day-time to a good paying basis. The curve for the evening hour indicates a good, broad, solid load, which shows the combination of six o'clock business, with the addition of a good solid evening load. Many stations after reaching the maximum point around six o'clock, rapidly fall off and never regain this point again for the evening. Here we have the illustration of clubs, theatres, churches, concerts and residences, lighting after supper, bringing up the load to its maximum point between eight and nine o'clock. The average load for the twenty-four hours, which is about twenty-five per cent. of the maximum, is a very fair one, and with the addition of the day load that will come on with the addition of power, will make this a model load diagram. The general run of stations shows as an average for the twenty-four hours, from twenty to forty per cent. of the maximum load ; the latter figure is very seldom reached. The writer knows of one station in which we have the latter figure, and where, if we eliminate one short half-hour around six o'clock A. M., we have the remarkable showing of seventy-five per cent. average load for the twenty-four hours. As to the workings of the engines in this station, indicator cards from running tests show the division of work on the cylinders as follows :—



LOAD DIAGRAM OF BROOKLYN EDISON STATION.

I. H. P. head end high pressure cylinder	........$63\frac{8}{10}$	h. p.
" crank end " " "	.......$60\frac{2}{10}$	"
" " low " "	...... $59\frac{2}{10}$	"
" head end " " "	.......$55\frac{2}{10}$	"
Making a total, I. H. P.	....$238\frac{4}{10}$	h. p.

with a boiler pressure of 110 pounds, revolutions 223 and load 1,200 amperes, which is the equivalent of 2,725 lamps, therefore giving for the indicated power furnished, eleven and one-half lamps per horse-power. This is for power developed, making no allowance for friction of engine and dynamo. The friction of the engine is less than 5 per cent. of its normal capacity.

Having in the above given a general outline of this plant, its cost and operating expenses, I now wish to call your attention to the points in connection with the type of engines, boilers, dynamos, underground system, etc., to be adopted in a station of this class.

In planning the engine power of a station of this kind, we first have to consider the question of using either the Corliss or high speed engine. Regarding the use of Corliss engines, we are frank to state our objections. Excessive first cost, ponderous machinery, counter-shafting, pulleys, clutches, etc., lead us to believe that these things are unnecessary when the problem is carefully considered from an unbiased standpoint. Assume for the sake of argument, that we can save five or ten per cent. in steam economy, if this is obtained at a cost, the interest of which amounts to more than this, we are obtaining it for no good whatever ; furthermore, there are many other problems in electric light stations which we have to carefully consider in this question of steam plant, one of which is reliability in operation, and being always ready for service. We should not design our plant for that capacity reached as shown on our load diagram, for only a short time in the twenty-four hours, but we must so design it to give this result for the average, that we have during the twenty-four hours. Even where we have a more constant load, as in exclusive arc lighting on municipal circuits, I think even here we need to carefully consider the problem as well.

High speed engines, so called, although they are not in piston speed any higher than the Corliss, but merely in rotative speed, have shown a considerable development and marked advance in the past year, and the next year is going to see even more development in this line. Owing to better workmanship, better designing and building than formerly, the prejudice which largely existed among old engineers against this type of engine, is rapidly wearing away. With the single cylinder engine under variable load we often obtain poor economy, but as compared with the Corliss, under similar conditions, allowing for the discrepancy in price, the result is not so disparaging. Now they are going further, and building compound and even triple expansion engines of this class. In the Brooklyn station we have one of the representative types of this class of engines, horizontal, compound engines.

These engines are built for high economy and economical work, and the guarantees made on them, I think, compare favorably with the guarantee on compound Corliss engines; at least three or four of the manufacturers of this class of engine stand ready to-day to guarantee from twenty-two to twenty-five pounds of water per indicated horse-power per hour. I do not know of any Corliss manufacturers who are willing to do any better. Engines of this class are as well built now in workmanship, and as reliable in operation as can possibly be desired. Added to this, we have the advantage of direct connection to our generators. Tests made at the Brooklyn station have shown that the engines have actually come up to the guarantee made on them, and that the plant there is showing, as compared with single cylinder engines, an economy of coal per unit of output from twenty-five to thirty per cent. better. In a station of this kind, the actual coal consumed per unit of output at the dynamos is considerably larger than is shown on a direct test where we charge the engine only with the coal it uses directly. The weekly records from stations of this class charge the horse-power output with all the coal used by the engine, pumps, condensers, well pumps, cleaning fires, blowing off boilers, etc., and where the former item is about three pounds of coal per horse-power per hour, we have in the latter case, making no allowance for the engine running empty, a result fifty per cent. greater than this. Economy in this line, however, is not going to stop at compound engines, as there are being built by at least two manufacturers, triple expansion high speed engines.

In connection with the triple expansion engines mentioned, we have to consider, again, the problem of the dynamos to be used. We can stay as at present, and belt to our dynamos, but I believe that the next large incandescent stations will not only include compound or triple expansion engines of 300 or 400 h. p., but will also have multi-polar dynamos, one or two being directly connected to the engine. By this I do not mean belted, but direct shaft connection through a flexible coupling. This, of course, necessitates the multi-polar machine, in order to secure the output with a slower speed. Engines and dynamos of this type can be installed in the space at present occupied by the engines alone. This means not only economy in building and real estate, but also in operating expenses.

In regard to boilers for such a plant, we do not know that we have any new economy to be hoped for in the near future. All we have to look for at present is improvement in detail of manufacture and the securing of better and dryer steam. We have two classes of boilers prominently before us for this work. We have, in general, first, horizontal tubular boilers, which we find in general factory use, to a large extent, throughout the country. Where we have plenty and cheap real estate, poorer attendance and moderate steam pressure, this class, in general, fills the bill. We find, however, that they are now even building them to work up as high as 125 pounds boiler pressure. When we come to construction of the boiler plant on expensive city property, where we are cramped for space, we are almost limited at once to some one of the types of sectional water tube boilers. In the Brooklyn station, we are practically limited to the consideration of this class, and we have not only 125 pounds but 150 pounds boiler pressure, and even higher. We have also the advantage of quick steaming under heavy changes in load.

We have to-day, brought before us in the underground systems, the consideration of what is to most of the companies their most serious problem, in the proper solution of which the best talent is being devoted. In the Edison underground system we have what is generally recognized as the most practical solution for circuits of less than 500 volts. We here obtain at a minimum of cost the most flexible system and local distribution from house to house, which has no equal. It enables you to take off services for local distribution from every twenty feet without in any way affecting the insulation on the main line, and being able at any time to disconnect these services and restore the main to its original condition. In any other system we have the problem of splicing and cutting of cables, which, at its best, is bad work. What we desire is not such a high insulation, as good, mechanical protection. As long as we can hold a moderate insulation with good mechanical protection, that is all we want. In Paris they have used bare copper conductors, supported on porcelain in a concrete conduit. This has worked satisfactorily in the main so far, but, of course, are very expensive. They are now proposing for all their increase, the Edison tubing for this class of work. In any system of cables drawn in we have the selection of a large class of conduits, but in my mind all we need and desire, as I have before stated, is mechanical protection for these cables, and the cheapest conduit that will afford this protection is all that is necessary. What is wanted especially is some system of local distribution for these higher tension circuits. The underground system installed in Brooklyn has a network of underground conductors in the mains and feeders of over twenty-five miles. This entire system is so arranged, distributed and connected in a net-work that, with a drop or resistance of one per cent. on the mains and ten per cent. on the feeders, we are able to maintain in the system practically a perfect regulation in the distribution of the current. This system stands to-day representing one of the most complete and perfect examples of work of this class. The largest problems that we know of in underground work are the proposed new extension of the Edison company in New York, and the underground system of feeders proposed to be installed for the West End Railway, of Boston. The copper alone for the latter amounts to over $1,000,000; and this question of the cost of the copper calls my attention to a fact which I desire to notice, that much of this question of bugbear on copper is uncalled for when we are considering the underground system. The entire copper used on the system in Brooklyn is less than one-fifth of the cost of the underground system first installed.

I do not desire to claim that the ideas for the class of work here represented and described, hold or represent all the perfection to be obtained in central station work. There are many points contrary to the ideas here outlined, which are very desirable; I have merely tried to call your attention to what I consider good work in this particular line, and hope that it will result in bringing forth the discussions and additions which are very beneficial in the consideration of these problems in the results to be obtained, and I would only add a tribute to the powerful and master mind whose work, from the commencement of this field of central station distribution, has covered the leading problems and points, and whose ideas to-day represent much of the good and very little of the bad problems which we have in this work. I refer to Thomas A. Edison, whose work, commencing in this field on the old Pearl street station in New York, over eight years ago, when the majority doubted, and but few believed in its successful carrying out, and while we find that station until within the past few months, when it was partially destroyed, successfully working, and even antiquated as it was, earning large dividends. He has still continued actively to impregnate his ideas on the work from that day to this, although he has not taken such an active part in its carrying out, but I think we may see him at no distant day, again taking a hand in this work, and bringing forth many new ideas in advancing the progress of the future.

CARBON TESTS.

BY E. F. PECK.

[Abstract.]

THE first electric light of any consequence was used by Sir Humphrey Davy in 1810. He had discovered that when the two terminals of a charged electric circuit were separated a short distance, an electric spark would pass between these terminals by evaporizing the material of which the electrodes were composed, and that the vapor thus produced would continue to carry the current between the electrodes, and that these vapors, together with the highly incandescent solid ends of the electrodes would emit a powerful light. The vaporized material bridging the space between the terminals of the electric circuit he denominated the electric arc, for the reason that these vapors would pass in a curved path between the two electrodes. Sir Humphrey Davy demonstrated this interesting phenomenon by using a great variety of material for the electrodes, and he found that the most brilliant effects were produced when the electrodes were made of carbons. The carbon used by him was charcoal made from various woods. It was found, however, that the charcoal from whatever wood it was made always had a considerable electrical resistance, and was so rapidly consumed that it could not be used for the production of arc lights for practical purposes. Other electricians took hold of Sir Humphrey Davy's discovery and their efforts were directed toward the discovery of material for the production of electrodes of greater durability and better conductivity. It was finally discovered that carbon deposited in the neck of gas retorts possessed a high degree of conductivity, and was exceedingly hard, and therefore would be very durable when used as electrodes for arc lights. Rods or pencils of this gas retort carbon were made and shaped at great expense and trouble, and they were found to be excellent substitutes for the charcoal electrodes; still these gas retort carbons could never be used on a large scale for the reason that they could be shaped to the required form only at a very great expense. The next step in the improvement of carbon electrodes for arc lamps were made in 1842, when Bunsen invented what he called the "Plastic" carbon as the negative electrode of his battery. The carbon electrode was made of various mixtures of powdered charcoal, molasses, sugar, etc. It could be shaped to any desired form, and was made by Bunsen in the shape of hollow cylinders and flat plates. When it was found that this carbon electrode could be used to advantage for the production of electric arc lights, it was at once substituted for the gas carbon. This substitution was not a universal one, for as late as 1873 and 1874, Professor Tyndall was in the habit of using gas retort carbons in the production of electric arc lights, although he complained that the production of his carbon electrodes involved great expense and trouble. The carbons burned at the Centennial Exposition in 1876 were of this material, but we have no data of their life or resistance. They were made by Carré, of France, and the current was from a Gramme machine. From 1843, when Bunsen invented his "Plastic" or moulded carbon, to 1879, many inventors of this country and Europe tried to improve on his discovery. Their chief object was to produce a carbon of greater and more uniform density and higher conductivity. English patents were especially numerous during this period, and their mixtures in the more enlightened state of the art, seem now very ludicrous. Though some labored at the problem nearly fifteen years, on the whole no great improvement was made. This poverty of result was largely due to the fact that the dynamo apparatus of the day was unknown. All arc lights were produced by currents generated by batteries. The modern arc lamp, with its simple but effective mechanism, was unknown. The arc light was only a curious laboratory plaything. The proper experimental condition to enable an inventor to produce good carbons did not exist, and the financial stimulus of commercial demands was wholly absent. The modern arc light carbon of commerce is hardly ten years old. It became a necessity as soon as the modern dynamo apparatus was completed and commercial lighting by electricity was seen to be coming in the near future. The problem may be said to have been undertaken in 1878. The first point was to discover crude carbon that was both pure and cheap. At the suggestion of Fayette Brown, of Cleveland, Ohio, his son, A. E. Brown, then experimenting for the Brush Electric Co., tried residue from petroleum. Careful experiment proved this to be the long-sought-for crude material, nor have the investigations of the past ten years found any better. The next point was to manufacture carbons of the requisite quality. Nearly three years later the Brush carbon was produced. The first cost of these was very high and the demand small. Where carbons are now sold by the hundred thousand they were then sold by the dozen. Like most new articles the process of manufacture was roundabout and tedious, consequently both the cost and market price of carbons ten years ago was very high, the first carbons selling as high as $125 per 1,000. I cannot learn that any tests were made of these carbons for resistance, brilliancy or even exact life. In those days manufacturers were well satisfied if they could make carbons that would burn fairly well, and gave other considerations very little thought, because they were relatively unimportant. Besides, Mr. Brush and his associates, there were several others in different parts of the country working at carbon business on different lines. At Ansonia, Conn., the Messrs. Wallace were experimenting with forced carbons, with much success, following the process of Carrè of France. This carbon was very dense and hard, and when sounded gave forth a ring almost like a bell. Not to mention many others, Mr. Thompson, of Newark, N. J., was also in the field, but clinging to gas retort carbons for his crude material, did not meet with the success achieved by his competitors. Since those early days of experimental work, manufacturers have paid special attention to reducing the cost, lowering the resistance, and increasing the brilliancy and life of the carbon. Early in the spring of 1889, at the suggestion of a representative of one of the large carbon manufacturers, I decided to base a year's contract for carbons on the comparative test of the best known carbons in the market. I made two or three tests, taking into consideration simply the life and resistance of the carbons as adapted to the system of lighting we were using. The tests were rather crude and not made for the purpose of booming any particular carbon but to satisfy myself as to what carbon I could best afford to burn. The final test was made with a group of Thomson-Houston lamps on a six and one-half ampere circuit. Two sets of carbons of each make were placed in the lamps and each lamp adjusted to the lowest point at which a quiet arc could be maintained. A record was made of the time of starting each lamp and they were then allowed to burn until all the lamps had cut themselves out automatically, by the burning out of the carbons. The electromotive force at the terminals of each lamp was recorded at intervals of half an hour through the day. The result of the test stated briefly, was as follows :

Lamps.	1 and 2.	3 and 4.	5 and 6.	7 and 8.	9 and 10.	11 and 12.
Average. e. m. f.	42.23	42.73	47.16	48.37	47.76	49.66
Average inches burned per hour.	1.23	1.46	1.44	1.57	1.72	1.69

As will be seen by this table, there was a difference of 7.43 volts or a saving of about 15 per cent. in the e. m. f. of the best over the poorest carbon tested, and a difference in life of .49 inches per hour or a saving of 29 per cent. In a station burning a thousand arc lamps this means a saving of 64.73 e. h. p. without considering the saving in carbons. The figures given above show very plainly the importance of such tests, and I would recommend that superintendents and managers of central lighting stations give this matter their consideration before adopting any special make of carbons.

APPLICATION OF ELECTRICITY TO STREET RAILWAYS.

FRANK J. SPRAGUE.

[Abstract.]

Scarcely 15 years, said Mr. Sprague, have passed since the beginning of a new era, the transmission of energy for light, power and the reproduction of speech. Of the progress of the first and last I need not speak, for the delegates of this convention are well cognizant of their history. But that great industry, the transmission of electricity for power, with its possibilities of all kinds, is of very recent development. Six years ago there were scarcely a hundred electric motors in operation in the United States for any purpose ; to-day there are no less than 15,000 in use, applied to not less than 200 different industries; and an industrial revolution is taking place equaling, if not surpassing, in importance that attending the introduction of the steam engine.

It is not my purpose to dwell at length upon the subject of the transmission of power by electricity in its general application, but to touch upon one branch only, that of railway work, reviewing very briefly its development in the United States, pointing out the salient features of successful operation, noting what has been already accomplished, and after some remarks upon the legal questions which have arisen, considering the possibilities of the future.

The modern electric railway may be said to have been born in Europe ; its babyhood was in Europe ; but in its youth and young manhood it is purely American. In 1881, Dr. Siemens, of Berlin, established the pioneer railway on the Lichtenfeld line in the suburbs of Berlin, and I believe it is still running. It was followed by other roads, some commercial and others for exhibition, erected by the firm of Siemens, and by the work of other electrical engineers. The Siemenses also established a line at Frankfort. The Hopkinsons established one at Portrush, Ireland. Another was established at Blackpool. This last was a conduit system. A double metallic overhead system was established in 1888 at Vevay, Switzerland, and recently the Siemenses have established a conduit system at Buda Pesth.

The first line in the United States for commercial service was a suburban line of two miles, built by Mr. Daft, at Baltimore, late in 1885, using a central rail. Other lines were established by Mr. Van Depoele in various parts of the country, using the single and double trolley system, with the trolley traveling upon and carried by the wire and connected to the car by a flexible cable.

In all this pioneer work direct supply was used, but most of the mechanical features and electrical details have given way to other and more efficient methods.

Of recent work three classes demand attention : one the system of independent units operated by the storage battery, and the other two direct systems of supply, one underground, the other overhead.

There is something very attractive in the proposed application of storage batteries. To store up conveniently a large amount of energy in a box, put it aboard a car, carry it around, and take out a greater or less amount of work, offers, when practicable, a solution of the street car problem for which we are all devoutly hopeful. But, commercially, the storage battery is still a long way from being a serious competitor of the direct supply. Great improvements have been made, but they have not much altered its character or weight, or the care requisite to get an economical return of energy. These improvements have made it possible to employ heavier charges without producing buckling, have made a rougher usage of the battery possible, and have in some instances much reduced the cost of manufacture ; so that the element of maintenance is less serious than a year or two ago; but it is still necessary to have about 3,500 pounds to propel an ordinary street car. This takes up space, and is a serious extra load. It requires frequent shifting, and its capacity and discharge rate are so limited that it is impossible to work upon grades which are at all severe. I believe it is possible with care to operate a storage battery on grades not exceeding, say, four per cent., and, with limited speed and daily mileage, at an expense about equal to that of horses, or a little less ; but yet at about double the expense required upon a suitably erected and properly operated overhead system.

Nowhere in the United States, that I am aware of, is serious storage battery work being done at present. The largest attempt was on the Madison avenue line, New York city, where about a dozen cars were run for a while ; but owing to legal complications only two cars are now running there,—with what daily mileage I do not know. In the service of overhead lines motor cars start out at five or six o'clock in the morning and run until midnight. Many cars make 150 or 160 miles a day, and some cars have even even made 180 and 190 miles a day. Half of this for storage battery work is good duty, but it is not up to the demands of street railway managers, and until the radical improvements which are promised are made, its field of application will be limited.

The conduit system of direct supply has been attempted in several places, notably at Denver, Cleveland, Allegheny City and Boston, but at all these places the experiments have proved disastrous and have been abandoned, save the short section at Allegheny City. In England, the Blackpool line, under special conditions, has been, I believe, fairly successful, and at Buda Pesth, the Messrs. Siemens have a conduit system in successful operation. There, however, the drainage is perfect, and a man is detailed for given sections of the track, and is continually employed in patrolling his section and clearing it out. Assuming good sewerage, the conduit can unquestionably be made to work. It becomes then a question of cost ; but for general application, especially in view of the fact that most of our cities do not have a sewerage system which can take care of the street drainage, the expense is prohibitory save on large systems under exceptional conditions. I look forward to the time when many existing well constructed and well drained cable conduits will become electrical conduits, and electricity will then score another victory.

The system, however, which has made marked advance is the single trolley overhead system, with universally flexible underneath contact, and this has been the growth of the past two and a half years. I think I can fairly claim for the Sprague company the pioneer place in this development; but the commercial development on the lines it laid down has been pushed forward with great energy by both the Sprague and the Thomson-Houston companies. The first work of the Sprague company, other than experiments on the elevated roads of New York, was done but a short distance from this city. A single car was started in 1887 on the Union Passenger Railway Co.'s line in St. Joseph, with a small 7½ h. p. motor, single geared, and adapted to run at a very high speed on a suburban extension. That road has seen nearly every change made in the system. It has been extended twice, and has both the old style motors and the more modern equipment. But all the work done on that line was, it may be said, purely experimental, and it was not until the 2d of February, 1888, that the Richmond road was officially opened. A radical departure was made from previous work, not only in the extent of the system equipped and the number of the machines operated, but also in the disposition and control of the machines, the system of overhead wiring, and the method of getting the current from the wire. The road was about 12 miles long, with 30 curves, some of exceedingly short radius, with grades running as high as 10 per cent., and with a road-bed utterly unfit for its traffic. The equipment was for 40 cars, requiring 80 machines, and to be operated from one station. When first proposed the attempt was regarded with ridicule, not only by street railway men but by electricians. The railway men thought it impossible for a self-propelled car to ascend a grade exceeding five or six per cent.; and that a 10 per cent. grade was out of the bounds of reason. As regards the electrical problems, the motors, instead of being placed on the car body flexibly connected by chain gearing or belts to the axles, were placed underneath the car, and flexibly geared to the axles. They were uncovered and exposed to the mud and moisture, and to all the accumulations which might collect in the street. They were built to run on a 400-volt grounded circuit, and to run in either direction with fixed brushes. Insanity was a mild term to designate the mental condition of one who made these proposals. The motor man was confined to his ordinary platform and the regulating devices there situated. A wire of one-fifth of an inch in diameter was extended over the track, and supplied at intervals of its length by a wire carried alongside the street where the strain upon the poles was least, and this main conductor was supplied at three or four central points by feeders from the central station. The current, moreover, was taken from this wire, not by a traveling carriage upon the wire, flexibly connected with the car, but by an arm reaching upward and pressing underneath the wire. This contact arm, which is now technically known as the trolley pole, was placed in the centre of the car and had a universal movement, resisting up and down displacement sufficiently to make a good contact with the wire, but at the same time free to follow all vertical deflections. In addition it had a lateral movement of considerable reach, offering little opposition to any side deflections by the wire itself.

Well, Richmond has passed into history. It has had its vicissitudes, it has had its victories as well. But it remains with all its crudities and with all the accidents which have marked its career, as the one great step in advance whose features in the main, have been followed in almost all the recent electric railways. Machines have been made larger, they have been made mechanically and electrically more perfect. Changes of detail have been frequent, but most of the characteristic features there outlined mark to-day nearly every electrical railway which is either in operation, in process of construction, or under contract.

The strongest opponents of electric traction two years ago are now its best friends, and the enterprise, for which it was then difficult to get a dollar investment, to-day demands the best thought and the most active energies of two great corporations and a number of smaller ones. The friends of the cable system are on the defensive. The advocates of the electric system are reliant and aggressive. Its flexibility, the ease with which it is extended, its adaptability to various conditions of service, its freedom from long continued breakdown, the marvelous advances which have been made in perfecting its apparatus, all insure its supremacy.

As to danger, the electric car is the safest possible vehicle, because of the remarkable facility of control. Touching the objections to overhead lines on the score of danger, which have been raised by municipal authorities and cited by telephone interests, they are, we may safely say, imaginary rather than real. Almost every employé of the contracting companies and a great many employés of the railway companies, including not only the linemen, and those whose business it is to work upon the electrical equipment, but the conductors and drivers, have received shocks from the lines of greater or less duration, and under almost every possible condition. Yet in no instance which ever came under my observation, or of which we have any reliable record, has serious injury resulted from the shock of the current itself. Experience seems to be quite ample to warrant the assertion that as ordinarily constructed a constant potential circuit of 500 volts is not dangerous to human life, and we can dismiss that question.

Reviewing the work of the past two years, that which was promised for electricity has been in the main entirely fulfilled. It has proved itself capable of doing the most extraordinary work under the most unfavorable conditions. Grades of 12½ per cent., and more recently of 14 per cent., have been ascended with loaded cars. Grades three miles long, varying from four to eight per cent., have been ascended by a motor car pulling a tow car. It has done work impossible for horses. It has enabled the running speed of cars to be increased even in crowded cities 50 per cent.; and on suburban routes speeds of 20 miles or more have been made. Experimental runs of 30 miles an hour on the ordinary street car with the narrow flange wheel have been attained; and on special experiments a speed of nearly 150 miles an hour has been made for a short distance. The electric car has shown that it can run faster on both up and down grades; that it can be gotten under way and stopped more quickly than a horse car; that with any given number of cars the mileage has been increased and the same time intervals made with a less number of cars. Many cars have made from 180 to 190 miles in one day. Horse space having been saved, the equipments occupy a third less space, and this fact, coupled with the ability to back when necessary and again quickly gain headway, has enabled an electric railway car in crowded and narrow streets to work its passage where a horse car would be at a dead standstill. Not only has the possibility of running down grade faster been established, but that possibility with a high degree of safety, because in the event of losing control of a car by the brakes, the instant reversal of the motor will bring the car to a standstill. This has frequently happened, and in one case, recently reported, the inspector stated that a car was going nearly 35 miles an hour on the down grade before the driver attempted to reverse his machine; but when he did so, he brought his car to a standstill with the loss of only one gear.

It can very properly be said that there have been many breakdowns; that machines have depreciated; that there have been exasperating troubles. True, these things have happened, and in case of defective workmanship and of careless inspection or management, they will happen again no matter what system of propulsion is adopted. The accidents which can happen to a motor come within a very limited category, and the liability of a motor to these accidents is being very rapidly reduced to a minimum, till it is becoming to-day the most perfect piece of machinery, capable of the longest continued use and a large amount of abuse. The very accidents which have happened—and I may say here that nine-tenths of the troubles are due to mechanical defects—and the very makeshifts which have been resorted to to overcome troubles and keep lines in operation, are the best evidence of the flexibility of the system and the perfection to which it will arrive. No other machine in existence has in so short a period of development, been brought to such a degree of perfection, is capable of such varied application, or can be so quickly and easily understood.

In a paper read before the American Institute of Electrical Engineers in August, 1888, and in some earlier communications, I made an estimate as to the expense of operating a 30 car road, dividing these operating expenses under two heads: (1), those belonging to the central station; and (2), what may be called the road operating expenses, the sum of the two constituting the total cost of motive power. In making this estimate I used extra care, and while preserving its accuracy, made every reasonable allowance that I thought necessary. The conclusion at which I arrived in the estimate under the conditions there given, was that the total cost of motive per car mile should not exceed $4\frac{8}{10}$ cents. I also stated that this was about 40 per cent. of the cost of operating by horses, under the same conditions. My estimate was considered too liberal in favor of electricity. Without going into details, I may state that reliable records of roads, under every condition of service, bear out the claims that I then made. I have the records of only a portion of the roads which we have equipped. Some roads see fit to make public these records. Others, and with a good show of reason, do not care to do so, because of the feeling that municipal bodies, in considering the granting of franchises, will not look at the increased cost of investment, but ignoring the manifold advantages to be gained by the introduction of electricity, for the public as well as for the company, are inclined to make unreasonable demands in the way of the reduction of fares, or require unnecessary and unprofitable extensions of lines. They forget that the reduction of one cent in a fare means a cut on 20 per cent. in the receipts of the company, and that a very remarkable saving of expenses must be made in order to meet this reduction of revenue, especially where there is an increased equipment on which interest must be earned. But suffice it to say that careful investigation will convince any candid man that the economic claim has been entirely supported, and the best elements of it is in the rapid adoption of this method of propulsion.

A few remarks may be in place relating to the interferences with other established interests which this new application of electricity has developed. Such conflicts, as electricity is applied to different industries, necessarily arise and result from the claims made by two or three enterprises to the same area of occupancy, whether of air or earth. There have been, long before electric railways became at all common, conflicts between the electric lighting and telephone interests. In the early days of electric lighting, and more particularly in that branch known as constant potential distribution, an attempt was made to use the earth for one-half of the circuit, precisely as was done and has been done for years in telegraphy. Practical experience, however, demonstrated that this was a mistake where incandescent lights were concerned, and it is manifestly a mistake where arc lights and high potentials are used. The objections on the constant potential incandescent circuit were pertinent because of the liability of fire in the buildings where the ground circuit was used, and the element of personal danger very quickly put an end to an attempt to use a ground circuit for an arc light system. The same cautionary reasons applicable to these two classes of industries do not, however, apply to overhead electric railway systems. The electric railway circuit is purely an external circuit. Its derivations are through the cars which it supplies. It is led into no dwelling; its fixtures are not within ordinary reach. It is carried in the open air, in full view in the most direct possible lines, and with only such supports as are necessary to make its construction safe. The whole construction of an overhead electrical system is materially simplified, and, in my opinion, made mechanically as well as electrically far safer by the adoption of a single wire, using the rails as a return circuit. The practical proof of the wisdom of this decision is the fact that about 90 per cent. of all the electric railways in the United States, use only the single wire. It scarcely seems necessary at this stage to go into the defense of this system. Its simplicity, the lightness of construction, the symmetry of outline, the size and strength of the poles, the fewness of the supports, the simplicity of all curve work, turnouts, crossings and sidings, and especially of all switch work and switch operations, are so manifest that elaboration of these features is unnecessary.

The use of the grounded circuit has unquestionably interfered with the operation of telephones which likewise use the grounded circuit. So long as electric railways were in an experimental stage, running perhaps in suburban districts, out of the way of telephone circuits, little or no attention was paid by telephone companies to their existence. The strides which have been made in the past two years and a half, bringing the railway system into the very heart of towns and cities, and into the forefront as a commercial enterprise, and the rapid increase in the extent and use of the telephone system, have brought the two interests in direct conflict, which conflict is solely because of their common use of that great reservoir of electricity, if we choose so to term it, or rather that great common medium for conducting it which has been used alike by railways, telephones and telegraphs since these industries were started.

The claim of the telephone companies, in brief, is that by right of prior occupation and of their vested interests, no electric railway or other circuit shall use the earth if interfering with their lines in any way. Their claim is far-reaching; it is of the broadest possible character, and, strictly interpreted, is an exclusive claim on the use of the earth for transmitting energy by electricity. That there is an interference with the telephone circuits by an electric railway circuit is undeniable, and the interference is annoying. The character of the interference is twofold. Part of the trouble arises from induction, that sympathetic response in the telephone circuit to any changes in the electrical condition of the railway circuit, and part to leakage, caused by the diverting through the telephone system of a part of the current which has been discharged into the earth and is on its way back to the central station.

The relative amount of these two interferences has been variously stated. On the part of the telephone company it is admitted that conduction or leakage is a source of trouble. They also admit that the use of any metallic return circuit, it matters not what, whether it be an individual circuit for each telephone, or a common metallic return for all the telephones, will obviate this or most of it. Even this much is admitted by the telephone interests with a great deal of hesitation, despite its perfectly apparent truth. But they go further. They claim that this is not the principal cause of trouble, but that most of it is due to induction, and that if a return metallic circuit overhead were put up by the railway company—that is, if a double trolley system were used—then the telephone troubles would all cease. The various attempts they have made in the courts have been with a view to either compelling the railway companies to cease operations or to so change their system as to abolish the use of the single trolley and erect in its place the double trolley system; or, on the other hand, to compel the electric railway company to pay for the necessary changes required in the telephone circuit to avoid the interference. No sooner was this issue presented than it was promptly met by the railway interests which I represent.

Now, what are the facts? First, as I have stated, there is unquestionably an interference between the electric railway and the telephone services; but of the character of this interference it seems to me that no intelligent man who honestly makes an investigation, seeking truth, and truth only, and unbiased by the commercial interests which have retained him, can have any reasonable doubt. The assertions made by the telephone interests leave little room for exaggeration on their part. Not only has the character of the interference been misrepresented, but the costs of any changes made necessary on the part of the telephone company to avoid trouble, or on the part of the railway company to change over its system, have been grossly misstated.

As a matter of fact, the trouble from induction is of the very slightest character, and that must be patent to any one who is familiar with this particular electrical action. Generally the trolley wire is situated in the middle of the street, anywhere from 20 to 30 or 40 feet away from the telephone lines. It rarely runs parallel to them except for a comparatively short distance, possibly two, or even three miles, but more often less. The current used upon this wire is not of that character which distinguishes some of the arc light circuits, but is of more or less even flow, and the abrupt and large changes due to change of load on the motor are comparatively infrequent. There is a very small change due to the variation of resistance of the armature of the motor, because of the different relative positions of the commutator blocks under the brushes, and there is likewise a variation due to the slight but rapid changes of counter E. M. F. set up by the motor when running. But although these changes can be detected inductively, provided the conditions are favorable—for instance, if both the telephone and railway circuits were wound around a common bar of iron—the character of the disturbance is not so serious as to preclude conversation. But the trouble which does really become pronounced is that which is due to the actual difference of potential which exists on different parts of the track circuit—in other words, at the terminals of the grounded telephone circuits. There is discharged into the earth, as I have pointed out, a slightly varying current. It may be at some point considerably removed from the station and in close proximity to the ground terminal of a telephone whose exchange is likewise grounded at another point much nearer, electrically, to the station than the point of discharge. The current reaching the rail has to travel back to the station, partly by the rails and partly by the earth. Both offer more or less resistance, and there is an actual difference of potential between the point of discharge and the station, rising at times to as much as 20 or 30 volts; but it is, of course, a variable potential, and the current which flows over that path is one which varies in its character. Having discharged the current in the earth, there is absolutely no limit to its diffusion. We desire, of course, that it should return by the rails, but no boundary can be placed upon it. A part of it goes through the rails, but some portions will go through the earth, through water ways, mineral veins, gas and water connections, electric light tubes, telephone circuits, rivers and canals, and, in fact, over any and all paths which offer it opportunity to return to the source from which it originated. The shortest geographical line between two points may be a thousand feet. The paths of the current between those two points may be anything from a thousand feet to 50,000 or more. But precisely as the rail current is thus disseminated or diffused in its return paths, so also is the telephone current. True, it is only a current of small capacity, so small as to interfere with no other enterprise or translating device except others of like character, but its diffusion is of precisely the same character and over the same territory and through the same classes of conductors as that of the rail current. Could the telephone current be limited in its path, and the claim of the telephone company be narrowed down to a specific section of earth, then, possibly, there might be some basis for a claim to the use of that section; but such a restriction is, of course, manifestly impossible. Hence, any claim the telephone interest makes to the earth must be vague; it must be all-reaching; it must be exclusive. It would seem that it has no more legal right to make a claim which prohibits a railway in the town in which the telephone circuits are operated from using the earth, than it has to make a claim that a railway in any other city with which the telephone may be remotely connected, shall be prohibited likewise from using the earth in that particular city, although it may be a hundred miles off. It is a well-known fact among electricians, and probably no better known than among the telephone people themselves, that, perfectly independent of railway enterprises, a far better service can be rendered the patrons of the telephone where a complete metallic circuit is used, and the use of the earth abolished. The telephone is the most jealous detector possible of all disturbances of electrical condition on the circuit which includes it. Its very function as a transmitter of speech depends upon this marvelous delicacy. As now operated in the majority of telephone exchanges, it is subject to continual interference not only from the railway circuit but from every electric light, power or telegraph with which it is brought into proximity. It is subject to interference from atmospheric changes and discharges. The telephone circuits themselves interfere with each other. Cross talk and false signaling are common. Almost all these troubles can be avoided, and the telephone service made far more perfect by using either the individual metallic return with the switch-board properly constructed for it, or the common return, which would make absolutely no change in the telephonic switch-board—what is known as the McClure device, the use of an artificial metallic ground or common metallic return of a resistance, low compared with the resistance of the instruments. The lower the resistance of this common return the less any interference of the telephones with each other. The cost of this latter method is a bagatelle. It should be put up by the telephone companies for the sake of their patrons, irrespective of any other consideration. Wherever intelligently put up the relief from outside interference has been almost absolute, and the testimony of parties who made complaint when telephone companies first sought to obtain an injunction against the railways is now emphatic as to the relief which has been obtained by this change in the method of running the telephone circuits. It is unquestionable that the telephone company is waging the warfare from the standpoint of economy, pleading the rights of vested interests, notwithstanding every telephone expert knows the great advantage to be gained from a metallic circuit, and notwithstanding the fact that sundry papers read at the telephone conventions not only admit that the metallic circuit is best, but give testimony from the exchange superintendents that wherever their patrons once use the metallic circuit and long-distance telephone, they are never satisfied thereafter to use the grounded circuit. It is likewise suggestive that the Bell Telephone company to-day advertises about 150 local stations in New York city equipped with the long-distance telephone and the metallic circuit. Since there is not an electric railway in the City of New York, their action in this locality could not have been dictated by interference from that interest.

Since both the telephone and the railway companies occupy public streets by public license, it is of course necessary to examine into the source of their respective titles and the character of their occupancy. The electric railway has proven a great advance upon any method of street car propulsion hitherto known. It has been shown to be economical, safe and advantageous as a method of public travel. It certainly cannot be said to be objectionable *per se*. It interferes less with the travelers upon the highway than many other methods of propulsion, and its very extended adoption shows us that it has been sanctioned by public authorities as a safe and proper method of travel. The single trolley system being used by nine-tenths of the street railways in the United States using electric motive power, certainly shows that practical experience is in favor of that particular method. As an improvement upon the method of propulsion it would seem that an electric street railway uses a public highway, occupies the same and enjoys the right of travel thereon, as of equal dignity with any or all other persons or vehicles upon that highway, and that this right of enjoyment is within the original purpose for which the highways were opened. On the other hand, it is pertinent to inquire what right or title a telephone company has in the street. By virtue of the original dedication of the highway they have no rights except that of toleration. Telephones and telegraphs are identical in contemplation of law and have been held to be an additional burden upon highways. In almost every case where this question has come up in the matter of telegraphs, such has been the decision. The statutes under which telephone or telegraph lines are permitted to be erected on highways, provide that while they may be so erected, the poles and wires shall not interfere with public travel upon the highways. Since this is true, the telephone companies are upon a public road not by virtue of right, but of toleration; not as the equals of the street railway, but subordinate to it. They occupy a secondary position, and this being the case, where conflict arises between the two, it would seem that the telephone interest must eventually yield, for its claim against any competitive enterprise is nothing less than a claim to the exclusive right of the earth, not to some section of it, because there are no limits to which the telephone wires may not reach, no boundaries to the portions of the earth which form a part of their circuits. Certainly no statute gives an exclusive privilege to a telegraph or a telephone company; and any claim for such an exclusive right, to be substantiated, must show an expressed or implied grant from some source, and the boundary as well as the source of that title. Not only this, but it must show that the title is exclusive. In view of the fact that the telegraph companies had used ground circuits for 30 years or more before the telephone was discovered, and that patents were refused for such use, it will be somewhat difficult for the telephone company to show the source of its title; and it is manifestly impossible to show the limits of the territory from which any other enterprise must be excluded, so that it will in no way interfere with the operation of the telephone system, for the telephone circuits being attached to the gas and water systems of the community in which it is located, the ramifications of such systems and of all the subterranean electric conductors of the earth in contact with these metallic conductors are unknown to science. How other electric currents entering the earth may do so without invading the charmed area of the telephone and disturbing its grounded wires no man can say, much less can the telephone people themselves. The boundaries, then, of their claim being so vague, it would seem that their claim itself must necessarily fail.

Within the past two years there have been, I believe, eight attempts made by the telephone interests to get an injunction. The first was in Akron, O., in the latter part of 1888, where the Central Union Telephone Co., of Chicago, attempted to restrain one of the Sprague roads by injunction. This was denied. The next suit was against the Harrisburg road and the Sprague company by the Penn Telephone Co. A number of common stockholders, I believe, were interested in both companies, and although the attorneys of the railway companies were fully prepared and desirous of seeing the case brought to trial, the case was abandoned and compromised for the very sensible reason that it would cost less on both sides to compromise than to carry it to the higher courts. The next attempt on the part of the telephone interests was in the application for an injunction against one of our roads at Chattanooga, Tenn. This injunction was denied. Then came a conflict in Salt Lake City, where many of the people were so interested that they said as between the telephone and electric railway interests, if the decision was against the railway company they would abolish the use of the telephone. Such heroic measures apparently were unnecessary, for the injunction was twice denied. Then application for an injunction was made in Cincinnati—and this will probably become a *cause célebré*—the injunction, on what ground I do not yet know has just been granted. This case will be carried to the higher courts.

In Eau Claire, Wisconsin, an attack was made on the railway interests under cover of a state law which the telephone companies had quietly gotten passed requiring a return insulated conductor for any circuit carrying electric energy. The injunction was there denied, for the telephone company had somewhat overreached itself, and found itself quite as much in the mud as the railway company might be in the mire so far as the law was concerned, because they were themselves the carriers of electric energy and were using grounded circuits, and consequently had no standing before the court. The last case with which we have been directly concerned is one at St. Joseph, which has not yet been tried. In Albany, where another electric railway company is operating, the telephone interest has succeeded in getting a temporary injunction. I believe this case, in which my own company is not particularly interested, except sympathetically, has been recently reheard and a decision on the merits is now pending.

With the records thus given it would seem that the electric railway companies have little to fear from the attacks made upon them by the Bell Telephone company. They are well within their right, and that being so their position must sooner or later be established beyond all peradventure. Often the same stockholders have been in both companies, and a sensible compromise has been effected, in which the telephone company has sometimes changed the route of its circuits, or put up a common return, or the companies have used each other's poles, and a just division of expense has been settled upon. This would seem to me to be the better plan wherever conflicting interests arise, and is one which I would recommend in all cases where the telephone companies are willing to recognize the justice of the legal position of the railway company instead of attempting as they have in the cases mentioned, to deny that right. A just compromise, but no surrender, should be the motto of the railway company.

So much for street car practice, and looking forward we naturally ask what will be the near future of the application of this remarkable agent? Already we have gone from one car units to trains of 2, 3 and even 4 cars in the street, and 40 cars have been operated from a single station. The next step will be the operation of some of the cable roads, then systems like the Underground Railway of London, the Elevated railways of New York, the Brooklyn Bridge system, and then suburban lines will be operated. But is this the limit?

I have been frequently asked whether, in my opinion, electricity will ever be used on trunk lines for through passenger or freight traffic? My answer is: Probably not, according to present notions of trunk line transportation, and not by present methods of train despatching. But with these qualifications I admit my hope and expectation of rapid transit under certain conditions. Let us for a moment consider a few facts.

Railway managers are constantly meeting with a demand for more rapid and luxurious methods of transit, and every effort which executive ability and financial expenditure within reason can devise is made to meet this demand. I think I can safely say that as steam railways are operated, a maximum speed of ninety miles per hour, and a running speed of sixty to seventy is all that can be hoped for in steam railway travel under the best conditions which can be provided. The limitations are too many. The maximum speed of a locomotive to-day is little more than it was twenty years ago. True, engines are larger and more powerful, but the increased weight of trains has made this necessary. To get pulling power there is a limit to the size of the drivers, and whatever their size there is a limit to the economical rate of piston speed and to the number of revolutions per minute. As the size of the driver increases, the centre of gravity of the engine is raised. As the steam demands become greater the difficulty of taking water and of firing grows more pronounced. Even now it requires the best work of a fireman, when his engine is pulling heavy load, to prevent the engine dying on the road, or at least falling far short of its duty. The increase of running speed has been obtained principally by cutting down grades, straightening curves, filling up ravines, replacing wooden structures by permanent way of iron or stone, the use of heavier rails, safer switches, improved methods of signaling, the interlocking switch and signal system, road crossing gates, the abolishing of grade crossings; in short, by improvements in detail and management which permit a higher safe speed over a more extended section of road, because of greater intrinsic safety, and of the greater degree of confidence inspired in engine driver, rather than by marked advance in the speed capacity, which should not be confounded with the pulling capacity of the engine *per se*.

With respect to electric motors, the question is not now whether a motor of sufficient capacity can be built, or efficiently and positively controlled, but rather how can the electricity be produced and supplied to the motor and at what potential can we work? We all hope to see the time when electricity can be produced economically from coal without the intervention of engines or dynamos; but I think that even then it will be quite likely that a central method of distribution will be the more advantageous. On the other hand, there are those who hope to see the storage battery so reduced in weight and improved in other particulars as to warrant its use in a large way in locomotives. For myself, I prefer to consider the possibilities of another method, the amplification and development to its full capacity of the present street railway practice, and for that purpose I will briefly consider a supposititious case, namely an express between New York, or rather Jersey City, and Philadelphia. The highest demands of such a service would require that, independently of the local travel, a through express track should be constructed by the most direct route possible between the principal localities, and every effort made to reduce the curvature and grades as much as possible. No matter how much it costs to build such a road, when the traffic is sufficiently large, it will pay to do it.

Suppose such a road to be an electrical one, and the method of supply to be from one or more central stations, the current being taken by a universally flexible underneath contact from a rod run above the car, and the return circuit made by means of the rails. What concerns us, as electrical engineers, is whether the cost of copper, the potential required, the losses on the line and the number of stations are such as would be prohibitory.

As regards the potential, other things being satisfactory, whatever pressure is demanded in the interest of economical and effective service will be used, and means will be found, consisting mainly in cars of construction, which will make its use for the purposes, and, as intended, safe and proper. We have, in these matters, to face the same questions that we have in the matter of steam pressure, or of railway speed. To accomplish the larger engineering feats necessary to meet the demands of economy and commerce; we will be governed more by belief in our power fully to subordinate a good servant to our will than by our fears of its vagaries.

From 8 A. M. to 9 P. M., a period of 13 hours, 21 regular trains leave the Jersey City station of the Pennsylvania road to run through to Philadelphia. Twelve of these make but one or two stops. The others make more or less stops according to the running schedule. Taking the through trains only, and allowing an average of say five cars to a train, there are in the 13 hours about 105 through cars despatched from Jersey City, or at the rate of one car every 7½ minutes, and of the through cars not making over one or two stops there would be one every 13 minutes. We will suppose an additional express track built, leaving the distance about what it is now, say 90 miles, but that the grades have been eased and the worst curves rectified. For the practical purposes of this paper I will consider that the road is level, that the cars are to be despatched in two-car units on a perfect block system, and to run through to Philadelphia with not more than one stop, at fixed intervals, and at a high average rate of speed, say sixty miles per hour. In the system I would propose—practically that with which I experimented some years ago—slight grades would make little difference in the general result, especially if the grade percentage, expressed as a whole number, does not exceed the quotient of the traction in pounds per ton divided by 20; because when $c = \frac{t}{20}$, where t equals traction in pounds per net ton, and c equals grade percentage expressed as a whole number, the work of traction and of lifting are equal. For example, suppose $t = 10$ pounds and $c = \cdot\frac{1}{2}$ per cent., and that we had on a double track one unit coming down the grade and the other ascending it, both at the same speed. Then gravity would be supplying just enough power to propel the car on the down grade at a fixed speed, and enough power to supply the lifting and traction work of the other car would have to be supplied, which would be just the amount required to propel both cars on a dead level.

Suppose the grade to exceed the ratio expressed above, then the car on the down grade would have an excess of falling energy, and this would be used in accelerating the speed of the car, or on the brakes, or it could be used by a process of reconversion for the purpose of supplying at short range part of the extra energy required by the ascending train. Just how this can be done is pretty fairly understood by electricians, but I will touch upon it again, because it is a feature of vital importance in determining the matter of motor control in a large system such as we are now considering, and because it illustrates one of the most beautiful features of this method of converting energy. No matter whether a machine be used for a motor or a dynamo, whether to convert mechanical energy into electricity or the reverse, the armature develops an electric pressure of potential which is dependent upon its speed and the effective strength of the magnetic field in which it is used. If this field is in shunt relation to the armature and in connection with the track circuit, we have by any of the well-known methods a means for independently varying the strength of that field. When such a machine is geared to a car, it can either drive the car, acting as a motor, or be driven by it as a dynamo, and in connection with any other similarly connected motor, or the central station generators, will form an electrical couple, either of which may be driven by, or drive, the apparatus to which it is connected. If the couple thus established is between the motor and the central station dynamo we have at one end a machine driven by a constant speed engine and generating an approximately constant electromotive force, and at the other end a machine of greatly varying speed, and with facility for increasing or diminishing the electromotive force which it generates. The result is an electrical differential which will establish a current between the two in one direction or the other, according as the pressure developed by the motor is lower or greater than that developed at the generating station. If the pressures are equal no current will flow between them. If the couple consists of two motors thus connected, then we have two apparatus, each of which is generating a variable electromotive force, and there will be a current between these or not according to their relative electrical pressures.* A large system is tied together in the most intimate manner possible. The tracks are cross-connected, the overhead conductors cross-connected, and we would have, in effect, what would correspond to two large planes, between which is moved at varying speeds a number of independent units these two planes being kept at a fairly constant potential by means of the generating station. All motors starting, running on a level, or ascending a grade, would be requiring current. All motors running on a down grade with just that velocity which the force of gravity would give them would require no current; and motors running on down grades of greater percentage than is required to give them power for traction, or motors slowing down, would be generating currents to aid in the general supply. No other system of distribution can by any possibility have this very remarkable interchange of energy. When running at a particular speed a slight movement of a regulating handle would make the motor receive from or give to the line currents in any desired quantity. The braking power of a motor thus acting as a generator is very powerful and the most perfect imaginable, because, unlike the ordinary methods, the brake does not operate if the wheels stand still, the very essential of the braking operation requiring the wheels to turn. It is a well-known fact that the most effective brake work is when the wheels do not skid upon the track, but when they are turning under the pressure of the brake; and contrary to the ordinary braking practice, the energy of the electric train instead of being thrown away, in the form of heat and using up the wheels and brakeshoes, can be made useful in the propulsion of other trains. I have tried this method of braking with such a degree of refinement that a heavily loaded car would creep on a down grade at a pace so slow that an egg could be put under the wheels and cracked and removed before the wheel would pass over it.

Having thus touched upon the characteristics such as I would propose for a railway system of this character, let us resume the consideration of the proposed line between New York and Philadelphia, and try to form some idea of the electrical pressure which would be required, the service which could be demanded, the number of cars which could be handled, the speeds which could be maintained, and the number of stations which would be required to operate the stations. We will assume, for the purpose of this investigation, an overhead conductor in the form of a solid rod one inch in diameter over each track, or, if you please, a smaller rod over each track, and a main conductor making up on equal weight, and a track of equivalent capacity. I take this arbitrary size because it is convenient for the purposes of our calculations and because it falls well within the limit of expenditure which such a system would warrant. For instance, the American Bell Telephone Co. has a line of long-distance telephone wires running from New York to Boston, a distance of about 300 miles, nearly three and a half times the distance which we are considering. On these poles are about seventy wires, each of No. 12 copper. The aggregate area of these conductors is over 300,000 circular mils, and the total weight of copper on this line, which is used simply for telephonic purposes, is about 40 per cent. more than the weight of two copper rods an inch in diameter running from New York to Philadelphia. If the investment is a reasonable one in the telephone system, cannot we certainly consider it a reasonable one in that larger field of the transmission of power of which we are now speaking.

As I have stated, of the number of trains which in 13 hours leave Jersey City for Philadelphia, 12 usually make only one or two stops. Allowing 60 cars, this would be about one car every 13 minutes. This interval of 13 minutes is nearly as short as would be desirable between cars running at an average speed of a mile a minute, no matter how perfect the block system, and it would be necessary to run these cars in double car units. We will assume for our purposes the size of a car such as is used on the elevated road in New York or the Brooklyn Bridge, which would, with motor and passengers, weigh from 20 to 25 tons, or a total of say 50 tons for our unit. The formula to determine the size of conductor for a single transmission of car is :—

$$c\,m = \frac{15,666\;n\,l}{E\,v\,\varphi};$$

where n = the number of horse-power, l = the distance in feet, E the potential at the motor, v the fall in potential and φ the commercial efficiency of the motor. If we assume the station situated in the middle of a line, that is, at the best point, and the work divided equally at the middle section on each side, then l being the length of line, we have the formula :—

$$c\,m = \frac{15,666\;n\,l}{4\,E\,v\,\varphi}.$$

This will be practically the same if the work is distributed over the entire line.

If more than one station is used, then the formula will become

$$c\,m = \frac{15,666\;n\,l}{4\,E\,v\,\varphi\,S^2};$$

that is, the size of the conductor would vary inversely as the square of the number of stations, if properly distributed. v may be expressed as a fraction of E, and for practical purposes we will let $v = \frac{1}{9}$ of E, and φ such that

$$\frac{15,666}{\varphi} = 16,800;$$

that is, φ = about 93 per cent. Then we have

$$c\,m = \frac{37,800\;n\,l}{E^2\,S^2}$$

which may be expressed thus, that the size of the wire varies inversely as the square of the product of the number of stations and the electromotive force.

We may also note that with any fixed size of conductor the electromotive force and the number of stations vary inversely—a somewhat important fact to remember.

We have another formula, one for the power required by a moving car, which is

$$h\,p = \frac{4}{75}\,w\,m\left(c + \frac{t}{20}\right)$$

where w = the weight in net tons ; m, the miles per hour ; c, the percentage of grade expressed as a whole number, and t, the traction in pounds per net ton.

As I have stated, we will assume in this formula that c equals zero, a consideration in which I am justified in express service on a road of the character I have outlined, with the relation of grades and traction given, and with the method of braking I have described. Our formula would then become, using 10 lbs. per ton as our average traction,

$$h\,p = \frac{2}{75}\,w\,m;$$

which, substituted for n in the distribution formula, gives us

$$c\,m = \frac{1008\;w\,m\,l}{E^2\,S^2};$$

or substituting for l, 5,280 d, d being the number of miles between stations,

$$c\,m = \frac{5,322,240\;w\,m\,l}{E^2\,S^2};$$

we have assumed for our conductors two rods an inch in diameter, and that the rail has the same resistance. Hence, substituting for $c.\ m.$, its value, 2,000,000 we have

$$E = \frac{2.66112\;w\,m\,d}{S^2},$$

or,

$$E = \frac{1.631}{S}\sqrt{w\,m\,d}.$$

It will be noted that m, w, and d, that is, number of miles per hour, weight handled, and distance over which operated, are all affected in the same way. Hence with any value of E and S we can vary the relative values of w, m, and d, so long as we do not disturb the product. That is, we can halve the number of miles and double the speed, or double the distance and halve the running speed, keeping the weight hauled the same, and so on. For w, the total weight, we can substitute the weight of each unit, c, and the number of units, b, thus making the formula—

$$E = \frac{1.631}{S}\sqrt{m\,b\,c\,d}.$$

For the line proposed, $d = 90$, and we have

$$E = \frac{15.56}{S}\sqrt{m\,b\,c}.$$

Taking our unit of two cars at 50 tons, the time intervals between them at 10 minutes, and 60 miles per hour as the mean speed, we have on the whole system 18 active units of two cars each, and $m\,b\,c = 54,000$, which substituted in our formula gives

$$E = \frac{3,615}{S},$$

which means that with one station in the middle the potential at the most or farthest from the station would be 3,616 volts, and near the station one-ninth higher. Can we handle it? Yes, in time, but perhaps not yet. Nor is there any necessity for doing so ; for if we increase the number of stations and go to a three-wire, instead of a two-wire system, making the track the balance of circuit, we would have the motor potential as expressed by the following table :—

Stations.		Motor Potential.	
Number.	Miles apart.	2-wire.	3-wire.
1	...	3516	1808
2	45	1808	904
3	30	1205	603
4	22½	904	452

which last brings us down to ordinary street car practice, which is only the beginning of what will be done in the effective handling of potentials.

So, after all, it does not seem such a serious electrical problem, and certainly not one to shrink from.

We can in another way illustrate the influence of the position and number of stations and the potential used. Suppose we had a station at Jersey City to supply the entire line at a certain potential over a conductor of the required size. If the station be moved to the centre, the weight of copper necessary is only one-quarter. Use two stations properly spaced and the weight is quartered again. Double the potential and the weight is further quartered. Now use the three-wire system and the weight is again quartered. So that by these very simple processes the original weight has been reduced to $\frac{1}{256}$th of the original.

I don't think I need to point out further the use of a proper determination of electrical values in a problem of this character.

We see then that the supposititious case is well within the range of possibilities. A 60-mile express service every 10 minutes instead of a 40 to 45 mile service every hour would revolutionize travel. Of the comforts of such a system I need not speak. That it will in the not very distant future be a fact, I know you all agree with me in hoping.

POINTERS.

.... VERY few of our countrymen realize that from one brief clause in the Constitution, guaranteeing protection to inventors for their inventions, more than all else, has resulted our great national advancement.—*Charles J. Kintner.*

.... STATEMENTS denying the possibility of results of great importance are useful as incentives to those in the same line who do not agree with their authors.—*Elmer A. Sperry.*

.... A CONSCIENTIOUS superintendent of an electric light central station should make it his business to see each splice made and finished.—*C. F. Dunderdale.*

.... THE discoverer of a truth is not he who guesses, though he may guess aright, but he who practically demonstrates a new fact, and thus compels its acceptance within the body of knowledge.—*Foree Bain*

... THAT is the best engineering, not which makes the most splendid or even the most perfect work, but that which makes a work that answers the purpose well at the least cost.—*Ashbel Welch.*

HOW TO MAKE ARC LIGHT CIRCUITS SAFE.

BY J. E. LOCKWOOD.

[Abstract.]

I DO not mean to convey the idea that arc light circuits are not, and will not always be dangerous, under certain circumstances, but I mean that with our present knowledge we can make our arc circuits so safe to our employés and the general public, that accidents will be of such rare occurrence as to attract no adverse criticism from either the press or the people.

We all know that the past year has been productive of more harm to electrical interests than any other year since we started, and there is no gainsaying the fact that the accidents have been in nearly all cases from arc light circuits, such as are usually termed "high tension circuits." Let us then benefit by the lesson we have had, and from this time forth see that nothing is left undone to prevent a recurrence.

Now the first thing to do is to locate the causes of dangers and troubles, and then to show a way to avoid them. As to the cause, we all know that the prime cause in almost every instance is a grounded circuit, and though there are other things to guard against, I think that if we can effectually guard against grounds, or be sure that the instant a ground appears, that fact will be known, and the ground located so that it can be quickly removed, the other causes will not be likely to result in much trouble. Now, to avoid the dangers resulting from grounds, we must first provide some means to enable us to know where "a ground" comes onto a circuit. It has been suggested to make a permanent ground in each circuit through a high resistance with an annunciator drop in circuit, so that when a second ground occurs a portion of the current will be shunted through the high resistance and drop and thus cause the drop to fall and indicate the coming on of the ground. An apt suggestion in regard to trying these devices has been made, viz.: that before asking others to try it, the inventor should be first connected to a high tension arc circuit and then make the second ground through his body. If this suggestion is carried out, I do not think this particular inventor will bother us any more.

Many other ideas have been advanced and tried to accomplish this result, but to-day I know of but one system that will indicate automatically a ground the instant it appears on a circuit, and that of itself creates no danger. This is the Rudd ground alarm, the invention of Mr. C. H. Rudd, of the Western Electric Co. of Chicago, and it is in use at the station of the Chicago Arc Light & Power Co., and I believe at a few other places. The Rudd system is as follows, the description and cut being taken from the *Western Electrician* of August 24, 1889.

[Mr. Lockwood here described the Rudd ground detector, which consists in the use of two condensers, a relay and a local bell circuit; one side of each condenser being connected to the + and — terminal, respectively, of the dynamo, the other sides of the condenser being connected together and to ground through a relay (usually an annunciator drop) which when actuated closes a battery circuit through a vibrating bell.] This device does not ground the circuit, but acts from the static effect due to a disturbance in the insulation of the circuit.

If this system is used a ground will be indicated the instant it appears, and we then have before us the problem of locating it. If, however, the above system is not adopted, the next best thing to do is to test every circuit regularly each day at certain specified hours, and I should advise a test every two or three hours while the circuit is in operation and two tests while not, the last two to be made, one the first thing in the morning, the other just at a sufficient time before starting up to give time to remove the ground if one is found to exist. If any circuits are operated all the time or nearly so, all four tests should be made while in operation at regular intervals.

I believe that the majority of grounds occur while circuits are in operation and that the best time to test for the same is at this time. In most cities there are many circuits that never have all their loops thrown on except when the circuits are in operation, and therefore this is the only time when the circuits can be tested in their entirety. To make these tests would require appliances to test circuits in operation and circuits not in operation. For the "dead" circuits, I would advise any of the testing sets now made by electrical instrument manufacturers, which are a combination of rheostat and galvanometer on the Wheatstone bridge principle, and which will test satisfactorily up to at least one megohm. A brass plate at the switch-board should then be provided and the same connected well with the earth. Now, by connecting one wire from your testing set to this ground plate and the other to a terminal of a circuit, your circuit and the earth become portions of the circuit and the ground connection between those two can then be measured. The total resistance less the resistance of the portion of the circuit between the set and the ground will be the resistance of the ground connection. No connection of less resistance than 100,000 ohms should ever be allowed to exist, and preferably not less than one megohm.

We now come to the locating of grounds when they are found to exist, and we will first take up grounds on dead circuits. To carry out this work we need the combined galvanometer and rheostat already spoken of, and the principle upon which the same should be applied is to divide yonr circuit into two parts by means of a cut-out box provided for this purpose, or other convenient means, and then to find upon which of these two parts the ground exists. After having determined this we can then connect the two parts of the circuit together and test next from a point about midway in the part upon which the ground exists, first separating the portion of the circuit leading to where the first test was made from that portion leading beyond this point; if the ground is still beyond this point, we must close the circuit here and again open it farther on and thus finally locate the ground. But if the ground is located on the portion of the circuit leading to where the first test was made we then know the ground to be between that point and the point where we are now testing. We can thus by dividing and subdividing the circuit locate the exact portion upon which the ground exists. As an adjunct to the foregoing, and as a convenient means of cutting the current off from a portion of the circuit without affecting the whole, as is sometimes necessary on account of a fire, it is advisable to divide each circuit up into four or more sections and to provide cut-out boxes so that any one or more of these sections can be cut entirely out of circuit.

In testing for grounds each section could then be tested separately and thus locate that upon which the ground exists, so that if necessary all of the circuit but the grounded section could be started up and then as soon as the ground is removed this section could be cut in.

In addition to providing these cut-out boxes loop circuits only should be put up, their advantages being too well known to need any explanation.

We now come to the locating of grounds upon live circuits. In Mr. Law's method the principle is that high voltages can be easily tested with ordinary appliances, such as incandescent lamps and ordinary voltmeters, if we test by steps. To do which, as many incandescent lamps of as nearly as possible a uniform resistance should be connected in series as there are arc lamps on the longest circuit to be tested. If, then, this series of incandescent lamps be connected across the terminal of the dynamo or circuit where the greatest difference of potential exists, as the incandescent lamps are connected in series and as there are as many as there are arc lamps on the circuit, each incandescent lamp will get the same number of volts as each arc lamp. Mr. Law states that he prefers using incandescent lamps of as nearly as possible the same voltage as his arc lamps, say of from 45 to 50 volts, so that when they burn at their normal candle power he will know that they are each getting the same number of volts as his arc lamps average. Now, before going farther, I wish to explain that as the current leaves the positive terminal of the dynamo, it is at its maximum voltage, which we will call 3,000 volts, and that as it passes through each arc lamp and is lowered at an average of about 50 volts per lamp, we have only to find the voltage of the current at the point of the circuit where the ground exists and then to divide the difference between the maximum voltage and the voltage at this point by the average voltage per arc lamp to find how many lamps are between the ground and the end of the circuit at which the test is being made. If, then, we have a list of the lights on this circuit arranged in the order in which they are connected, and stating which is the positive and which the negative end of the circuit we have only then to count off the lights and thus locate the ground.

This is substantially what is done by Mr. Law, with the simple difference that as he has means for cutting down the number of incandescent lamps in the series, he therefore connects one end of the series to a ground plate and the other to one end of a circuit, and if there is any indication of a ground, he then cuts down the number of incandescent lamps in the series until those left in the circuit burn at their normal candle power. A number of these then correspond to the number of arc lights between the end of the circuit from which the test is being made and the ground. For proof the test is repeated from the other end of the circuit.

My objection to this system of testing is based upon two reasons, first, because low voltage incandescent lamps are used that take about one and one-fourth amperes to bring up to normal candle power, and thus create a danger by the liability of this amount of current when passing through a light ground to cause fire, and the possibility of accident to persons who may come in contact with the circuit, being tested at a point far enough removed from the end at which the test is being made to cause serious results. What we want is to remove all the danger we can, not add new ones.

My second objection is based upon the very point wherein Mr. Law finds his system does not work satisfactorily, viz., that his system is not suitable to locate a weak or high resistance ground.

Now we should at least be able to test up to 100,000 ohms, and as with a voltage of 3,000 we could only get a current through this high resistance equal to 3,000, divided by 100,000, we could thus only get three one-hundredths of one ampere, and we could consequently use a system that could be operated by this amount of current. Now, to make our ground the least factor in the test, and as we would have only about one-half our incandescent lamps or high resistance coils in circuit in most tests, we must use resistance coils, and make them of such a resistance that 30 will equal at least one megohm, and thus each one would be about 33,000 ohms. As this high resistance is necessary to apply this system satisfactorily, you can all see plainly why I do not approve of the incandescent lamp system. If, however, incandescent lamps are used for ground testings only, those of the highest possible resistance and that use the smallest fraction of an ampere are suitable, and of all the styles now on the market the eight-candle power 110-volt lamp is the most suitable, because if, as many of these lamps are used as there are arc lamps in circuit, they will each only get about 50 volts, and consequently about one-tenth of one ampere, and will thus enable us to test up to a certain resistance equal to the maximum voltage of our circuit, say 3,000 volts, divided by the amperage, one-tenth of an ampere, which would be 30,000 ohms, a great increase in range from the low resistance lamps, which only enabled us to test up to 2,400 ohms. If lamps are used we should also use a dead-beat volt-meter, such as made by the Weston Electrical Instrument Co., and it should be connected in shunt around the first lamp of the series, which should be of enough higher resistance than the rest of the series to make it a resistance when connected in multiple with the volt-meter, just equal to that of each of the other lamps of the series. We could then, when making our test, cut out of circuit the incandescent lamps until the volt-meter indicated as nearly as possible the voltage which our arc lamps average. The number of incandescent lamps still remaining in circuit would then correspond to the number of arc lamps between the end of the circuit being tested and the ground. I would much prefer thus using a volt-meter and high resistance lamps to using low resistance lamps and bringing them up to normal candle power. This outfit could also be used, to find the average voltage of arc lamps on any circuit, and having once determined this point, and also how many lamps the line is equal to, and then test and find out at any moment how many lamps are being used on any circuit, and, if we are running a number of circuits from one dynamo, we could then find how many lamps are burning on each circuit, and plan our changes and combinations understandingly. A great improvement on this system would be a volt-meter to read up to five or six thousand volts, such as Mr. Law says can be made by the Weston Electrical Instrument Co., and the amount of the improvement would depend entirely upon the fraction of an ampere used to operate this instrument. The smaller the fraction the greater the improvement. With such an instrument the coming on suddenly of a ground when a test is being made, even if at the opposite extreme of the circuit, would do no harm to the instrument. This instrument should be as nearly as possible dead beat, so that in testing for a swinging ground the instrument would indicate accurately the voltage at the ground, even if the connection only existed for a moment. We now come to a system of testing which I think a great improvement over those already mentioned, except in one particular, viz.: the testing for swinging grounds. For this purpose the extremely high resistance and high capacity, dead beat volt-meter I consider better than anything else. This new system I had the fond belief up to a few days ago was original with myself, but I find the old saying, that "there is nothing new under the sun," has been again exemplified by my finding that practically the same system is in use at the stations of the Arc Light & Power Co. in Chicago, it having been put in, I understand, by Mr. Rudd of the Western Electric Co. of that city. The system in brief, is similar to the Wheatstone bridge, as the principal is to form a shunt circuit between the terminals of the arc circuit by means of from sixty to 100 coils of high resistance connected in series, and then by means of any very high resistance galvanometer finding the point on the shunt circuit from which no current will flow to grounds, then by noting at what point on the shunt or testing circuit for which this neutral point is the ground, it can easily be located. In applying this system I would provide means for cutting out of circuit any number of these coils with the idea of using at each test only as many coils as there are arc lamps burning on the circuit at the time of the test. Then when the neutral point is found you can see at once, without figuring, between what lamps on your circuit the ground exists. The advantages of this system are: First, it creates no new dangers; second, the question of how high a resistance ground can be tested depends simply upon the sensitiveness of the galvanometer; third, it is quick and accurate, and cannot be damaged by grounds suddenly coming on when testing. Now as a necessary adjunct to any of these systems of testing, there should be prepared a list of the lights and service on each circuit arranged in the order in which they are connected in the circuit, and stating which is the positive and which the negative end of the circuit. With such lists a competent lineman, when notified that there is a ground so many lamps distant from the negative or positive end, as it may be, of a certain circuit, should have no difficulty in quickly locating it, and to enable him safely and quickly to do this, he should be provided with a high reading volt-meter, so that by going directly to the point where he thinks the ground exists and testing from the circuit of the ground with his volt-meter he could tell whether the ground was very near or not, and if not about how many lamps were between this point and the ground. Then by testing again a little further on he would immediately see whether he was approaching or leaving the ground and thus could quickly locate same. In conclusion, I would say that I firmly believe that if we use such a system of testing and equip our circuits with good lightning arresters, and some such device as the circuit openers lately brought out to disconnect the dynamo from the circuit when the current ceases for an instant through the breakage of a wire or any other cause, and then see that our employés use these appliances and do their utmost to keep all lines clear of grounds, we will have few accidents, and the press will have little or nothing more to say about the dangers of electricity.

CORRESPONDENCE.

NEW YORK AND VICINITY.

Resumption of Arc Lighting.—Overhead Lines Improved.—The New Interior Conduit.—Electric Search Lights on Sound Steamers.—Electric Lighting in the Metropolitan Museum of Art.—The New York Telegraph Club Seeking New Quarters.—Another Subway Explosion.

THE subsidence of newspaper clamor regarding the overhead wires has been followed by the resumption of arc lighting in all parts of the city. The lines have been put into an improved condition, but are not yet up to the standards prescribed by expert Wheeler, who does not care to assume the responsibility of accident by certifying them. Affairs are now moving along smoothly, although an accident might create another sensation. There was a slight fire at the entrance of some wires into the Pearl street Edison station a few days ago, but the item was placed in obscure position in a Sunday paper, and its demoralizing effect was not so perceptible as it would have been had it appeared on the first page with a display head.

The new "conduit" for interior wiring, which has just been brought out by Mr. E. H. Johnson, for general use with any system of distribution, seems to be a good safeguard against fire from inside conductors. Several severe but satisfactory tests of its fire and waterproof qualities have been made.

The recent disaster to the steamer *City of Worcester*, which ran on Bartlett's Reef, New London, during a dense fog, has led to the introduction of electric search lights on the steamers of the Stonington line, the first boat equipped being the Rhode Island.

Considerable difficulty has been experienced by the executive committee of the Metropolitan Museum of art, in determining the best arrangement of the incandescent lamps with which the entire building is to be lighted. Various methods were proposed by different members of the committee, and finally the wire men were given instructions to fit up different rooms according to the various plans suggested, after which the full committee made its choice. The work was rapidly pushed, and the museum will soon be thrown open Tuesday and Friday nights.

Judgment for $101,484 was docketed January 28th in the County Clerk's office against the Bentley-Knight Electric Railway Co. It is in favor of the Thomson-Houston Electric Co., and was obtained in Supreme Court last year on four notes of $25,000 each made by the defendant.

The New York Telegraph Club's rooms, corner of Fulton and Church streets, have been set on fire twice, and some very valuable relics destroyed which cannot be replaced. An effort has been made to secure suitable rooms elsewhere down-town, but without success so far.

Another subway explosion occurred on Sunday, January 26th, in the vicinity of Broadway and Forty-second street. No damage was done, but it is significant that these explosions occur with such frequency that an accident insurance company is now using an illustrated cut in which a flying man-hole cover, a column of smoke, and a demoralized pedestrian are conspicuous; the moral, of course, being that notwithstanding the wires are likely to be buried, danger still lurks in the highway.

NEW YORK, February 25, 1890.

PHILADELPHIA.

The Muddled State of Philadelphia Legislation on Electrical Wires.—Electric Heating.—Electric Lighting in Germantown.

DESPITE the fact that council's negligence killed a good bill in 1887 designed to bury beneath ground electric wires, enough law was enacted previous to that time to mitigate greatly the situation. In fact, the law was clearly designed to do away with overhead wires.

On the 22d of March, 1880, an ordinance was passed conferring upon indviduals and corporations the right to lay underground conduits as receptacles for telephone, telegraph and electric wires. Then the matter slumbered for two years. On June 18, 1882, an ordinance was passed which read as follows :—

> "Prior to the first day of January, 1885, all poles and wires erected for telegraph, telephone and electric light purposes by firms, corporations or persons other than the city of Philadelphia shall be removed from the streets of the city of Philadelphia.
>
> "It shall be unlawful after the above date to erect or maintain any poles for the above-mentioned purposes in the streets of the said city excepting as provided for in foregoing sections so far as the same relates to the city of Philadelphia.
>
> "Any corporation, person or persons, excepting the city of Philadelphia, erecting and maintaining any poles and wires for the above purposes in violation of the provisions of this ordinance shall forfeit and pay fifty dollars for each day each of said poles is maintained, to be recovered as like penalties are now recoverable by law."

The date of the enforcement rolled around, but it is still a dead letter, despite the fact that in 1884 city solicitor Warwick, in an opinion delivered upon the ordinance, stated that no legal obstacle to its enforcement existed. This state of affairs shows that there exists a lack of executive as well as legislative interest.

By virtue of an ordinance passed February 16, 1886, the chief of the electrical bureau is authorized to issue permits for the erection of such electric light poles and wires as may be required for the lighting of public streets. Providing, and mark well the provision, "that none of the poles so erected shall be used for supplying light for private purposes."

A very interesting exhibit was made in the exhibition room of the Master Builders' Exchange a few days ago. It attracted a great deal of attention. It is an electric car-heating apparatus, electrical cooking stove and an electrical boiler attachment. The cooking stove resembles an ordinary skillet on an iron frame work, with a tin cover which will retain the heat and odor.

Anything can be cooked on this appliance that can be cooked in an ordinary range. The heat is intense, and the stove no more trouble than a common incandescent lamp. The car heater looks like a waffle iron 6 x 24, and is expected to throw out sufficient heat to keep a standard size railroad coach comfortably warm. A very small dynamo will suffice to heat an entire train of cars

The Electric Light Co., of Germantown, which is erecting a large building for its plant at Armat and Cumberland streets, expects to have everything completed for the running of machinery by March 1st.

In a recent letter the poor quality of gas with which this city is supplied was mentioned. Here is the way a well-known hotel proprietor jokes about it. He has obstinately refused all overtures of an electric light company to illuminate his place, and his plea is that there is absolutely no danger in using the gas that is now served in this city. "Even danger of asphyxiation is avoided," he says. "A fellow locked himself in one of my rooms the other day and turned on the gas with the intention of taking his life, but imagine his surprise the next morning when he was awakened by the pangs of a fierce appetite. Why that gas is absolutely wholesome."

BOSTON.

The Brush-Swan Co.'s Victory.—Number of Public Arc Lights in Boston.—Meter Service Demanded in Chelsea.—The Public Lighting Controversy; the Aldermen Refuse Pole Privileges to the Suburban Light and Power Co.; an Appeal to the Courts by that Company.—The West End Electric Road.—The Gas and Electric Light Commissioners' Report.—Electric Search Lights on Sound Steamers.—An Experimental Port-Electric Plant.—A Paper by Mr. F. M. Gilley, on the "Electrical Treatment of Sewage" at the Society of Arts.

THE Brush-Swan Electric Light Co., of New England, said to be owned by the Westinghouse people, having defeated the Brush Electric Co., in a suit for the specific performance of contracts, have thereby forced the Brush company to relinquish all its business in New England.

From the annual report of the superintendent of lamps, it appears that there were in use in Boston on Dec. 15, 1882, 214 electric lights; Dec. 15, 1883, 381; Dec. 15, 1884, 401; Dec. 15, 1885, 446; Dec. 15, 1886, 501; Dec. 15, 1887, 577; Dec. 15, 1888, 704; Dec. 1889, 798. The distribution of the 94 lights which have been added during the past year has been as follows: City proper, 32; South Boston, 11; Roxbury, 15; Charlestown, 6; East Boston, 5; Dorchester, 15; Brighton, 10; total 94. The number of 798 electric lamps forms but a small part of the 13,810 public street lamps, yet the cost of comparative maintenance is as follows: 1888—Paid for gas and oil lighting and care of same $374,828, paid for 704 electric lights $151,413; 1889—Paid for gas and oil, lighting and care of same $363,931, paid for 790 electric lights $180,895.

On the 27th of January the state gas commissioners gave a hearing at the city hall in Chelsea, on the petition of Joseph B. Everdean and others that the Chelsea Gas Light Co. be compelled to furnish incandescent electric lights to its customers by meter. Mayor Champlin and Frank M. Gilley appeared for the petitioners, and William G. Peck represented the Gas Light company. Mayor Champlin, in his opening, said the petitioners were some of the best business men of the city, and charged that the Gas Light company discriminated, in some places charging 25 cents per month for lights, and in other places $1.25 per month. Mr. Peck, for the company, stated that if a true meter could be found the company would readily adopt it.

The aldermen of Boston have finally disposed of the question of admitting the Suburban Light and Power Co. to do business in the city. The committee of the whole board held two lengthy sessions February 10; and at the meeting of the board later on the same day, the result of the committee's deliberations was made known. Two reports were made by the committee.

The majority report, recommended that the minority report of the committee on electric wires, made Jan. 27, be accepted. The minority report of Jan. 27 recommended "leave to withdraw." It called attention to the remonstrances which had been filed by a large number of business men against increasing the number of electric light wires in this city, and said that the board of fire commissioners, the board of fire underwriters and insurance men generally were opposed to the proposed increase. The minority report (committee of the whole, February 10) which was submitted, stated that by the opinion of the corporation counsel "the Suburban Light and Power Co. can legally contract and furnish electric lighting in the City of Boston, as it may obtain locations for from the board of aldermen." The minority reviews the circumstances of the award of the contract to the Suburban company by the superintendent of lamps, and says that "if there was no other reason for granting the petitioner's prayer, good faith and fair dealing with individuals demand that the bid accepted by the superintendent of lamps be ratified by any action which is necessary on the part of this board, but the more so, in this case, since the citizens in the particular districts to be affected are practically unanimous in favor of such action." The minority recommended the passage of the order granting the locations, with the amendment that the poles shall be similar to those known as the "Providence" poles. Without discussion the board proceeded to act on the reports. The majority report prevailed by a vote of seven to five. The "leave to withdraw" thus bestowed upon the Suburban Light and Power Co. means simply a refusal to grant the petition.

The directors of the company by no means give the matter up. They had made contracts for additional apparatus and had secured the old Globe Nail Works on Norfolk avenue for a power station, on the strength of the mayor's action.

An order of notice, returnable February 18, has been issued by Judge Field, of the Supreme Court, upon the application of the Suburban Light and Power Co. for a writ of mandamus to the mayor and board of aldermen of Boston, to compel them to grant locations for poles as petitioned for by said Suburban company. Mr. Albert C. Burrage, treasurer of the company, gives the following history of its connection with the matter: "In response to the city's advertisement bids were handed in Dec. 30, and after mature deliberation and consideration by the mayor, the corporation counsel, and the superintendent of lamps, the contract was finally awarded to our company on Jan. 9. The petition for the additional pole rights was placed before the board of aldermen Jan 20, and was referred in due course to the committee on electric wires. A majority of the committee reported in favor of the petition at the next meeting, but the board, feeling that there was a great public interest in the matter, directed that a public hearing be given. At that hearing it was shown that public sentiment in these districts was almost a unit in favor of the petition, and therefore the officers of the company cannot but say that the vote of seven to five, taken by the aldermen to-day, was a great surprise to them and will unquestionably be looked upon as a severe blow not only at the interests of the City of Boston but at its good name. Although entirely aware of the enormous pressure which had been brought to bear against the petition by interested rival companies, we did not question but that the merits of the case in favor of the petition were so strong that the aldermen could not do otherwise than grant it."

Mayor Hart is reported as saying that though the Suburban company is practically killed by the aldermen's action, the city will not be the loser, as the present contractors have shown an extraordinary eagerness to retain their present position even at the 40-cent rate.

The Suburban Light and Power Co. had proposed to place their wires underground in the business portion of the city. In the course of the hearings given in the matter, much interesting information was brought out touching the electric light business in the large cities of the country. Professor John P. Barrett, of Chicago, gave facts and figures concerning Chicago electric lights and his opinions thereon. D. R. Walker, of Philadelphia, gave the history of underground wires in that city. Both gentlemen strongly favoring the undergrounding of electric light wires.

The West End road are perfecting and extending their electric motor system with great rapidity.

A novel test of the power of the electric motors in use on the West End street car system was made on Jan. 29. Three ordinary passenger cars were hooked together, two of them being loaded to the ceiling with bags of meal, huge coils of heavy rope and other compact and weighty articles. The combined weight for each car was estimated at 10,000 pounds. The chief interest of the test centered upon the steep grades at Chardon and Cambridge streets, near Bowdoin square. After the tracks were well sanded, the train was started, and the Cambridge street grade was easily conquered, as was subsequently the Chardon street grade.

The Quincy and Boston Electric Street Railway Co. have just elected officers as follows: President, John Q. Adams; treasurer, Arthur Burnham; clerk, F. H. Smith; directors, the above-named gentlemen and Josiah Quincy, W. G. A. Pattee, W. T. Whitman, F. H. McDonnell, W. A. Hodges, John A. Duggan and Winthrop Coffin.

The fifth annual report of the board of gas and electric light commissioners has been presented. In the state there are 75 gas companies, 26 of which have the right to supply both gas and electricity, and 100 electric light and power companies. Seven gas companies have been authorized to engage in electric lighting business, and there have been six cases before the board on appeal from the decisions of the mayor and aldermen and selectmen of as many cities and towns. The year was an active one for those engaged in the electric lighting business. There were 44 new electric light and power companies, and four new companies for the manufacture of gas and the electric light incorporated.

The steamer Rhode Island of the Stonington line has just been equipped with a Huntington search light, for use when a fog, mist or snow prevails. Pilots say that they have seen the projected beam of light 18 miles. The instrument is placed on the roof of the pilot house, and is worked by the pilot from within. Its candle-power is 3,000. The Massachusetts is also to have one of these lights.

The New England Port-Electric Co. are building an experimental plant of their system of conveying mails and packages in a large field on the line of the New York and New England Railway, between Mt. Bowdoin and Harvard St. stations. The track is about one mile in length, with two curves, the radius of the lesser being 200 feet with grades, switches, etc., to correspond with the conditions that will exist when used for commercial purposes. There is a power station so located that the track passes directly through its centre at a distance of about two feet from the floor, with a lookout tower, from which the entire circuit of the track is visible. It is equipped with a Sturtevant 20 h. p. engine, an "American" dynamo for lighting purposes, and an Edco dynamo to furnish current for the cars, wound for a pressure of 1,000 volts. The cars will be about 12 feet in length, 10 inches in diameter, and of one-tenth of an inch steel, supported on two wheels and steadied by a third on top. The total weight of this size car with its load will be about 200 pounds. The wheels are about 10 inches in diameter, and will run upon ball bearings which have been tested at a speed of three miles a minute without overheating.

At the meeting of the Society of Arts, February 13, at the Institute of Technology, Mr. Frank M. Gilley read a paper on the "Electrical Purification of Sewage." Mr. Gilley described the process used in England, and illustrated the method by experiment. The organic matter in the sewage is decomposed by the nascent oxygen and chlorine and may be filtered out. The experimenter tells by the appearance of the liquid when to stop the current. The sewage is then filtered and allowed to run into the river. About 24 h. p. is required to treat successfully 1,000,000 gallons of sewage per day. The second process is by means of filtering through sand and coke alternately, the coke being charged with electricity, introduced by means of carbons. Both processes could be used in conjunction. Blackboard drawings were used in illustration.

BOSTON, February 15, 1890.

CHICAGO.

Delegates to the Electric Light Convention at Kansas City Entertained at Chicago on Their Way.—A Dynamo Plant Substituted for Batteries in the Western Union Telegraph Co.'s Chicago Office.—The Chicago Electric Club; a Paper by Mr. Sperry on High Tension Motors.—The Meeting of the Western Electric Railway Association Postponed to June 11.—A New Storage Battery Plate.—City Officials Want Their Telephone Service Restored.—Corporation Notes.

THE special electric limited train, with its party of delegates to the Kansas City convention of the National Electric Light Association, reached Chicago, February 9th. Several gentlemen representing the Chicago Electric Club, met the train at Englewood, and assured the travelers that they would receive a hearty welcome in Chicago. When the party reached the station, they found carriages waiting to convey them to the rooms of the Chicago Electric Club. A large number of guests and club members who had gathered in the rooms, cordially welcomed the eastern delegates.

After a brief informal reception, the party gathered in the assembly room. President F. G. Beach, of the Chicago Electric Club, in a few well-chosen words gave the visitors a hearty welcome. Mayor Cregier made a short address, in which he alluded in a good-humored way to the World's Fair, saying he had no doubt the New York gentlemen had brought with them the warrant giving the fair to Chicago. He excited a laugh by saying of Chicago, that it was second in commercial importance in the country, and in point of territory "Heaven only knows how large."

In response to calls, Dr. Robert Amory, of Boston, George M. Phelps, of New York, Dr. A. F. Mason, of Boston, A. J. De Camp, of Philadelphia, and F. E. Degenhardt and B. E. Sunny, of Chicago, made brief speeches, heartily acknowledging the courtesies of Chicago, and its Electric Club.

Lunch was served, after which the informal reception was continued. One of the ornaments of the assembly room was a star formed of incandescent lamps. Music was furnished by a mandolin orchestra. During the afternoon many of the delegates visited points of interest in the city. A number inspected the electric light plant in the Auditorium.

The special train, with two added coaches for Chicagoans, left the station at five o'clock, for Kansas City. The delegates were unanimous in the opinion that the reception formed an exceedingly pleasant break in their long journey westward. At the close of the convention, many of the eastern delegates returned by the way of Chicago, and were entertained by friends at the club.

The Western Union Telegraph office in Chicago, will hereafter obtain its current for operating its instruments from dynamos instead of from batteries. The batteries had been accumulating until they had reached the number of 25,000 cells. They were scattered about the building and required no little attendance. It was therefore determined to make an installation of dynamos.

The plant consists of 19 Edison machines; 15 of them, under normal conditions, run at 70 volts and are the regular Edison No. 2 dynamos, wound for 125 volts at 1,800 revolutions. These generators are run at 1,200 revolutions, so that the reduced potential of 70 volts is obtained. Two of the machines are wound for a potential of from 5 to 10 volts, and two are wound for 15 to 30 volts, the speed in each case being 1,250 revolutions. The dynamos are driven by three Sprague motors, one of 10 h. p. and two of 15 h. p. capacity each. In addition to the ordinary rheostats, these motors are provided with resistances which are in shunt to the series coils. By this arrangement a nice adjustment of speed is secured. Current for the motors is taken from the Edison central station circuits.

At the meeting of the Chicago Electric Club, February 3, Mr. Elmer A. Sperry read a paper on "Operation of Electric Motors With High Tension Currents." In the course of his paper, Mr. Sperry said:—"For the transmission of power from one point to another there can be no question as to the utility and great advantage of employing high potentials. I speak now of the transfer of power from one point to another as contra-distinguished from the distribution of power for domestic or like purposes on a widespread scale. I, however, see no reason why in the near future, this latter system also should not be prosecuted along the lines of high tension currents, inasmuch as the phenomenal progress which has characterized electrical engineering enterprises in the past will bring the question of insulation to a point where danger to life and property will almost entirely cease to be an element to be considered. This will doubtless be brought about, too, by the utilization of safety devices in the central plant, as well as throughout the construction."

Mr. Sperry contrasted the relative advantages of transmitting power by constant current and constant potential, assuming in each case a potential of 3,000 volts. Mr. Sperry concluded that the constant current system was in every way the more desirable. A spirited discussion followed, in which the constant potential men had an opportunity to express their views. The meeting was one of the most interesting ever held by the club.

The Western Electric Railway Association announced that it would hold a meeting in Chicago on January 29th. As there were only four members present on this date it was decided to adjourn until June 11th.

Mr. H. G. Osburn, of Chicago, recently received a patent for a new form of storage battery plate. The London *Electrical Review*, in referring to the patent, says: "At first sight it would appear as though the plate were composed of two grids, so placed in relation to each other that the openings in one coincide with the points of intersection of the ribs in the other. Instead, however, of there being two plates, the grid is cast in one piece. Some time during last year J. S. Sellon showed us some plates of his own, identical in every detail with that of Mr. Osburn. Which of these gentlemen claims priority of invention?"

At a recent meeting of the Chicago city council the mayor and comptroller were instructed to direct the Chicago Telephone Co. to replace the telephones recently removed from police stations and public offices.

The Hyde Park Electric Light and Power Co. has decreased its capital stock from $500,000 to $100,000.

The Bear Electric Co. has been incorporated in Chicago with a capital stock of $3,000,000 by S. J. M. Bear, N. H. Hauchett and A. P. Willoughby. The company is formed to exploit a dynamo invented by S. J. M. Bear.

CHICAGO, February 19, 1890.

ST. LOUIS.

The City Lighting Contract; Trouble with the Contracting Company.—Electric Light Deals.—The Laclede Gas Company's Electric Plant.—Lamps Stolen and Broken in the City Alleys.—The Lindell Railway Co.—Other Railway Notes.—The St. Louis Electric Power Co.—The Western Electrical Supply Co.—The Citizens' Electric Light and Power Co. of East St. Louis.—The New Brighton Electric Light Co.—A Municipal Electric Plant at St. Charles.

THE Municipal Electric Light and Power Co. are having a rather stormy time with the Board of Public Improvements on account of a change from low tension to high tension system, the city contract having been awarded with the understanding that a low tension, or short arc system would be used. The promoters of the company were closely identified with the Indianapolis Jenney Electric Co., and the Jenney system was the system expected to be used. The advantages of the Jenney low tension system were set forth to the board in a very forcible manner. Lately it became known to the board that the lighting company had changed their plans to a high tension system—the Wood system of the Ft. Wayne Electric Co. This change in plans together with the apparent slow progress in completing their station, caused the board to apprehend that the lighting company were not acting in good faith, and the vice-president of the company, Mr. Chas. A. Sutter, was cited to appear before the board on February 18, to explain the delay and change of plans. Mr. Mortimer Taylor, the legal adviser of the lighting company appeared, and explained that their company had really undertaken a contract of greater magnitude than they had expected, that the time fixed for the work to be completed was too short. Mr. Jas. I. Ayer, superintendent, explained the progress and present state of the work and also the change from low tension to high tension, which was occasioned by the absorption of the Indianapolis Jenney Electric Co. by the Ft. Wayne Electric Co. last October. The Ft. Wayne company at that time were supplying a low tension system, which has since been superseded by the Wood improved high tension system. Mr. Rorison, secretary of the Ft. Wayne company, stated the reason for their change to be that the low tension lamp required a very close regulation of the length of the arc, which was a difficulty that the Jenney electricians failed to remedy, and that as the improved high tension system was far superior in every way, they had adopted it. These explanations did not entirely satisfy the board. The president, Col. Flad, asked if the real reason was not that the high tension system was cheaper to operate than a low tension system. This was denied by Mr. Ayer, who stated that they wanted to use a live system, one that is in general use, and that the low tension system had become obsolete. The board will make a test of the two systems and possibly make a trip to Cincinnati to see the Wood improved high tension lamps which are used there, in order to settle the matter in a practical way.

The Hollins syndicate, of New York, have sold out their entire interest in the St. Louis Illuminating Co. and the Municipal Electric Light and Power Co. to Laudenberg Thalman and Co., of New York. This leaves the ownership of these two companies in the hands of Laudenberg Thalman and Co. and Seligman and Co., of New York, and Jas. Campbell and other local capitalists of St. Louis. The withdrawal of Hollins and Co. was caused by a difference of policy of the two factions which could not be harmonized. This deal will probably lead the way to the consolidation of the two companies into one corporation, styled the Consolidated Municipal Electric Light and Power Co.

The electric department of the Laclede Gas Co. are pushing work at their permanent station, and will probably be able to start up early in March, at which time the temporary plant will be transferred to the new quarters. This company will use Williams's triple expansion condensing engines and will, therefore, require a plentiful supply of water. Their station is favorably located for the purpose on the river bank, and a tunnel is being driven through solid rock into the river. A shaft has been sunk at a point midway between the station and the river, and the work is now being carried on in three headings. The river tunnel will not be completed in time for the starting up in March, and the engines will therefore be used at high pressure until the tunnel is finished.

Both the Missouri Electric Light and Power Co. and the electric department of the Laclede Gas Co., who are lighting the alleys of the city, have suffered much breakage of lamps by the malicious action of boys, and not a few lamps have been stolen from the sockets. A few prosecutions which are now underway, will probably put an end to such depredations. Aside from this the alley lighting is going on successfully in every way. The inductive disturbance to the telephone service which was caused by the alternating currents of the Missouri Electric Light and Power Co. has been almost removed.

A bill authorizing the Lindell Railway Co. to extend their Washington avenue and Choteaw avenue sections to Forest Park has passed the municipal assembly, and now awaits the signature of the mayor. The bill authorizes the company to use the overhead system of electric power, the company having already adopted the Sprague system. Construction will be begun at once and pushed rapidly to completion. Mr. F. D. Berry, a Johns Hopkins man of '88, has been appointed electrical engineer of the Lindell Railway Co.

A bill authorizing the Benton Bellfountain Railway to change to cable or electric power, has passed the municipal assembly and has been signed by the mayor. The company favor electric power, but as there is some uncertainty about getting the privilege of erecting overhead wires in the central part of the city, they may have to adopt the cable.

The Short Series Railway is again in operation on the south end of the Broadway line.

Track laying and overhead construction on the Union Depot line, and also work on the power house and new car sheds is progressing rapidly.

The new gas scheme—the Metropolitan Gas and Electric Light Co.—have failed to make a satisfactory showing with their new process of gas making.

The St. Louis Electric Power Co. are erecting a power station on the corner of 2d and Christy avenue which is expected to be ready for occupation by April 1. Since the destruction of the Guernsey Scudder building last December, they have occupied temporary quarters in the basement of the Exposition building, using the Edison dynamos of the Exposition building for supplying their circuits.

The Western Electrical Supply Co. have opened an office and salesroom at 310 N. 3d street. T. J. Wilson is president and manager, and W. F. Henderson vice-president. They deal in electrical merchandise of all kinds.

The Citizens' Electric Light and Power Co., of East St. Louis, started up their station on February 8, with one 600-light Slattery alternator and one Ft. Wayne Wood arc dynamo of 60-light capacity. This company secured a contract for lighting the City of East St. Louis with arc lights, and the entire number of lights are used for this purpose. Another 60-light dynamo will be installed shortly. The station occupies a very substantial brick building erected for the purpose with adequate steam power; two Westinghouse engines of 80 and 100 h. p. are used.

The New Brighton Electric Light Co., of East St. Louis, has been incorporated. Capital $20,000. P. W. Abt, president; Martin Benzen, vice-president; T. L. Fecket, secretary and treasurer.

At an election held on Tuesday, January 21, the City of St. Charles, Mo., increased their indebtedness in the sum of $150,000 for the purpose of establishing an electric light plant to be operated by the city.

ST. LOUIS, February 19, 1890.

PITTSBURGH.

The Authorities of Youngstown, O., Examine Electric Lighting in Pittsburgh.—The Mill and Mine Electrical Equipment Co.—Success of the Sprague Motors on the Pleasant Valley Railway.—Other Railway Notes.—Trouble in Starting a Cable Road.—The Allegheny City Municipal Plant.—Visit of Electric Light Men to Pittsburgh on their Return from Kansas City.—The New Town of Wilmerding to be Lighted by Electricity.

A COMMITTEE of municipal authorities from Youngstown, O., composed of D. Atchison, chairman; M. Oberdorfer, I. G. Smith, George E. Rose and I. G. Edward, were in this city a few days ago for the purpose of investigating the Pittsburgh system of electric lighting. They also inspected the alternating current incandescent light plant of the Allegheny County Light Co. in this city and in Allegheny City. After paying a visit to the Westinghouse Electric Works they returned home. Their object in coming to this city was to get pointers here with a view of erecting a municipal plant at Youngstown.

An application for a state charter has been made by the Mill and Mine Electric Equipment Co. of this city. The incorporators are Messrs. Walter A. Giles, John S. Scully, J. W. Carnahan, W. J. Burns, J. V. Patton and F. W. McKee. This company intend to carry on an electrical construction and supply business. They own the Hercules mining machine, an apparatus which was lately brought out and is now used in the production of coal along the Monongahela valley in several mines. Its great advantage is the feature of economy. It is claimed to enable the mining of coal at less than one cent per bushel. Each of these machines is supplied with a Tesla motor, the company having made a contract with the Westinghouse Electric Co. to supply this motor.

Since the Sprague electric motor has been started on the Pleasant Valley street car line in this city, electricity has become the popular motive power for street cars in Pittsburgh and Allegheny. The system has proved a great success so far, that is, without considering a couple of accidents which cost two horses their lives and the burning out of a few dozen of telephones and fire alarm boxes. It is now very likely that electricity will be adopted by all the other street car companies. Even the traction companies, it is rumored, will soon exchange the expensive cable system for the electric motor. The second avenue line, where the Thomson-Houston motor has been adopted, will commence operations March 1.

The managers of the central traction road are experiencing a great deal of trouble in getting their system into operation. The road has been finished since the first of February, and several trial trips have been made since, but every time new difficulties have presented themselves, which retard the successful running of the cars. The road consists mainly of several very steep hills. But with all that the company is still confident of making the cable a success before long, and when such improvements have been made the city will have the third cable road.

The Allegheny City municipal electric plant is now rapidly being built, and it is expected that the entire station will be in operation by next June. The power house on Braddock street is almost completed, and the installation of the machinery will shortly be commenced. The capacity of the plant will be 3,000 incandescent lights and 300 arcs. The plant will be run by the city with the Westinghouse alternating current system.

A large number of the delegates to the Kansas City Electric Light Convention stopped off in this city on their return to the east. While in Pittsburgh all gathered under the wings of Mr. Morris Mead, the superintendent of the bureau of electricity, who accompanied the visitors over all the interesting sights, and there are many of them—of the gas city. The central station plant of the Allegheny County Light Co. was inspected, and the guests were also taken over the Westinghouse Electric Works. The visitors were very much impressed with all they saw here, and they expressed themselves not a little astonished at the great progress Pittsburgh has made during the last few years as an electrical city.

The city council of Allegheny has granted an ordinance permitting the Pittsburgh and Manchester Street Car Co. the right to change their motive power to either cable traction or electricity.

Wilmerding, a suburban town of Pittsburgh, will be lighted by electricity in a short time. This is an entirely new town, situated along the Pennsylvania railroad. It was built by the Westinghouse Air Brake Co., which has located its new works there. The North American Construction Co. has been given the contract for the construction work of the plant. The central station will start with a Westinghouse alternating current dynamo of 1,500 incandescent lights, and a Westinghouse arc light machine of 60 lamps. A 100 foot iron tower will be put up in the works with six arc lights.

PITTSBURGH, February 20, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

DEWEY'S CATALOGUING SYSTEM.

[118.]—Professor Osmond seems rather unjust in his criticism, in the February number of the ELECTRICAL ENGINEER, on Mr. Dewey's classification of engineering sciences, and it is probable that, unless better arguments than his own are advanced against it by the gentlemen who are invited to protest by letter, the classification will not be changed. Mr. Dewey has evidently either consulted competent authority before making his classification or, more probably, has borrowed it from an authoritive source.

Professor Osmond would certainly not maintain that when a species in a botanical or zoological genus attains a certain commercial importance, it should be formed into a genus by itself; yet that a similar thing is not done in another case excites his indignation.

On the other hand, and most inconsistently, Mr. Osmond complains that the name invented to differentiate that small part of engineering that at one time was not military engineering, should be omitted. In rural districts the writer has met surveyors who pride themselves upon being civil engineers, and some graduates of colleges and engineering schools who occupy minor engineering positions, or none at all, are very tenacious of the title; but where you find an engineer of note it will generally be found also that he has differentiated his title so that it means something definite, which that of civil engineer certainly does not. It is true that the title has yet an existence in the designations of public officials and is yet given as a degree; but the master of the black rod is still an important personage, and almost any college confers the degree of master of science. What is true of the title is still more true of the generic name that, in the day when one man could practice them all, embraced in their entirety the statical and dynamical sciences then developed.

It is to be regretted that the proposed substitution of dynamical for mechanical did not take place, and that more schools did not follow the lead of the University of Pennsylvania in substituting the degree of dynamical engineer for that of mechanical engineer; the march of progress is so rapid, however, that it will not be long before either title will be, as the science has already been, so differentiated that it will occupy the same position that that of civil engineer does now,—more a mark of dilettanteism than the designation of a practicing engineer. When the other specialities under dynamical engineering shall have acquired sufficient commercial importance, they in turn will be differentiated by professional names, and the sooner this takes place the better, as the result, or rather cause, will be the substitution of an exclusive course in the schools, strictly appropriate to the profession, as in the case of electrical engineering, instead of the present inclusive one given under the name of mechanical engineering. In any event, however, the scientific basis of all of the professions in the classification in question as given by Mr. Dewey, will rest on the general laws of dynamics or mechanics,—a fact that commercial importance or specific titles cannot change.

Assuming that the criticism is due to the supposed implied precedence given to the specific title of mechanical engineer as conferred by some schools, it may be asked if an examination of the two courses where given together by any of the several leading technical schools, will not show that from this point of view the criticism is equally unjustified. Such an examination will show that the greater part of the course of an electrical engineer is what was formerly considered an exclusive qualification for the degree of mechanical engineer; and, moreover, that of the remainder of the course of the former a good part is of practical value to the laboratory electrician only, rather than to the practicing engineer. In other words, the graduated mechanical engineer would require a comparatively short supplementary course in electricity to place him on an efficient footing with the graduated electrical engineer, while to the passed student of electricity, *per se*, a course almost equal to that of the mechanical engineer or its equivalent would be required to enable him to enter the same profession on a proper footing. That this should be so, follows from the fact that a plant may run for months without any derangement of its strictly electrical parts, while the boilers, engines and various mechanisms, including those about the electrical apparatus that are purely mechanical, will require constant attention, adjustment and repairs; its installation is similarly almost entirely a question of mechanical, as distinguished from electrical knowledge, and in no profession, perhaps, are special details so definitely settled beforehand for the engineer as are all the purely electrical ones by the laboratory expert or inventor before the electrical engineer, as distinguished from the former, takes hold. Thus, from this standpoint also, the divorce suggested would be an unnatural one.

To resume, electrical engineering is essentially a branch of dynamical or mechanical engineering with a specialty, electricity, from which it derives its name, and the so-called mechanical engineering of the schools is the same with, in practice, a specialty which latter will in time probably give rise to a differentiated name and title for each branch, as in the former case.

If Mr. Dewey has erred at all, it is in not following the scientific method implied in the classification of the dynamical sciences by similarly embracing as sub-divisions, under the head of statical engineering, some of the branches that are assigned as divisions.

W.

BROOKLYN, N. Y., February 15, 1890.

CANDLE POWER AND WORK.

[119.]—We are sometimes told that the radiation of the incandescent filament or arc is the pure, ethereal essence of light; the *spiritus lucis*, a manifestation of the ultimate energy of the universe, exhibited indeed through matter, but unencumbered by, and dissociated from the comparatively gross mechanism of combustion which requires an external source of heat to initiate a series of operations which finally result in the production of light.

The more sober minded of us are wont to regard these expressions as merely the effusive rhetoric of an electrical enthusiast; but a little consideration will show them to contain some truth as well as poetry. In our older methods of obtaining light by burning fats, oils and gas, the light is often but an insignificant fraction of the total work of the chemical and physical processes involved in, and indispensable to, its generation by these means; while in the electrical method the light is the main thing, there being no irrecoverably wasted products which only offend the senses, vitiate the atmosphere and consume power.

We know that heat is but an expression of the mechanical work absorbed by the friction or impact of masses or particles of matter upon one another, and observation shows that those bodies which do most work—*i. e.*, produce most heat during combustion

—give the least light. Thus, if we burn equal weights of hydrogen, coal and dry wood, we find that the gas evolves more heat than any other known substance while its flame is the least luminous of all flames; the coal yields more light than, but less than one-fourth the heat of the hydrogen; and the wood, giving far more light than the coal, produces but half as much heat.

The following table copied from the address of Mr. W. H. Preece, president of the British Association, delivered before the Bath meeting of that body, in 1888, clearly shows the amount of power per photometric unit consumed by the various substances now commercially used in the generation of light.

Substance.	Watts absorbed per candle-power.
Tallow	124
Wax	94
Sperm	86
Mineral oil	80
Vegetable oil	57
Coal gas	68
Cannel gas	48
Electricity, glow	3
Electricity, arc	0.55

From this we see that the production of light and heat are inversely proportional to one another, and this rule holds good for the radiations of the glow and arc lamps, for; though no combustion takes place in either of them, yet the quantity of matter working, producing heat in the filament, small as it is, is nevertheless great compared to the amount of carbon vapor developed and made incandescent between the poles of the arc.

This is a long step towards the solution of the problem of obtaining light without heat, which we may reasonably hope will be accomplished by the electrical engineering of no distant day; but when this is done it will not be as great an advance upon the arc light of 1890, as the incandescent filament of the present time is beyond the mediæval tallow dipped rush of the literally dark ages. HOWARD PEACOCK.

New York, February 1, 1890.

POINTERS.

.... WITH the hope of reaching remunerative results, experiments are tried by commercial companies on a scale and at an expense that could not be compassed by the physicist. What results might be reached if such experiments were always directed by scientific knowledge!—*W. A. Anthony.*

.... I HAVE seen in one of the largest hotels in New York, lighted by its own plant, the large Edison dynamo being run with blocks of ice on the bearings to keep them cool. This the engineer told me was the way he always ran the machine.—*G. S. Ram.*

.... I HAVE no hesitation in saying that if any marked improvement has taken place in the management or in the arrangement of the telegraphs of this country through my exertions, I believe it has been greatly due to the contact I have made with the energy and go-aheadedness of our friends on the other side of the water.—*William H. Preece.*

.... I HAVE never yet met an American electrician who has come over to this side of the water who has not admired something that we do, and gone back feeling a wiser man.—*William H. Preece.*

.... I DO not think there is really very much difference between American engineers and English engineers. It is the conditions of the countries that are different, and the engineers over there have adapted themselves to the conditions.—*G. L. Addenbrooke.*

.... OVERHEAD wiring, properly done, combines economy with simplicity and efficiency.—*Frederick Reckenzaun.*

.... THEORY is an effort of the imagination to account for operations that are in themselves invisible and insensible, but which result in facts which are observable and known.—*William H. Preece.*

.... JUST as an enormous advance was made in literature when signs for each idea were replaced by a comparatively few letters making words, so I am inclined to think a second great advance was made, when ideas, however complicated, were expressed by combinations of two signals only.—*Professor W. E. Ayrton.*

.... TO spend millions of dollars for an idea, or to satisfy an unreasoning or an uninformed public opinion is bad engineering. —*Ashbel Welch.*

.... HOWEVER useful the term "electrical" efficiency may be to those whose object it is to sell machines to the engineer, the "efficiency" is the useful output of electrical power divided by the mechanical power actually given to the machine.—*John Perry.*

LITERATURE.

Absolute Measurements in Electricity and Magnetism. By Andrew Gray, M. A., F. R. S. E. Second edition, revised and enlarged. London and New York: Macmillan & Co., 1889.

THE appearance of this volume at this time will be somewhat of a surprise, no doubt, to those of our readers who recall the recent publication of the first volume of Professor Gray's larger work under a similar title, which was reviewed at some length in our issue of June, 1889. In the preface to that work Professor Gray described it as an extension of his smaller book, which, published in 1884, had long been out of print, and added that the design of the smaller book would be so extended as to make the new work a fairly complete treatise on the absolute measurement of electric and magnetic quantities.

In the preface to the present volume it is explained that although it was intended that the larger work should supersede the original small book, a demand for a second edition on the original plan has led to its preparation, notwithstanding that the second volume of the more comprehensive work is now in press. In this new edition the contents of the earlier one have been almost entirely retained, although the order of arrangement of the subjects has been changed, and many of them have been considerably amplified; while much new matter from the larger work has been added. The volume has thus been about doubled in size.

The main purpose of this work, like that of its predecessor, is to explain, both theoretically and practically, the measurement of potentials and currents in absolute measure, and their application to the graduation of instruments used in practical work. The absolute units of measurement of magnetic and electric quantities are defined at some length, and it is shown how from the fundamental units the practical units of current, quantity, potential and resistance are derived. Rules are given for the calculation of currents and resistances in derived circuits, together with some novel methods of determining resistances which are not usually described in text books; while the measurement of energy spent in the circuits of dynamos, motors and secondary batteries, and the determination in absolute units of the intensities of powerful magnetic fields receive brief but careful consideration.

The measurements described are for the most part refined laboratory processes involving the use of elaborate apparatus. Thus in order to illustrate the process of graduating the scales of measuring instruments the electric balances, electrostatic voltmeters, magnetostatic current meter, and quadrant electrometer of Sir William Thomson are selected as types. No other instruments are described or even referred to, and to such an extent is the work of Sir William Thomson set forth in these pages that one may easily get the impression that the volume is in part a eulogy of that distinguished philosopher's achievements.

While it is evident that methods suitable for calibrating one type of current and potential instruments must be applicable to the calibration of other types of the same class, it would certainly not have been out of place in a work of this character to indicate some of the more tried and less expensive types of measuring apparatus. Especially as in the earlier edition of this work Professor Gray then limited himself to an elaborate description of Sir William Thomson's new graded galvanometers. Experience has since proved—in this country at least—that these instruments are unreliable and wholly unsuited to the practical work for which they were intended. Their design was defective in almost every particular, from the wooden bases which warped and stood unsteadily on three badly distributed supports, to the thin semicircular directing magnets, whose moments were continually changing and practically needed to be re-determined whenever a careful test was to be made. Moreover the movement of the magnetometer, by which the sensibility of one of these instruments was varied, could not be accurately adjusted because of the lack of suitable facilities, while the method of attaching the flexible electrodes was awkward and inconvenient. Not a hint of the existence of any of these defects was let fall in the first edition, while in this edition all reference to these instruments has been simply omitted, and descriptions of these later valuable, but complicated and expensive, instruments substituted.

While the subject of electric and magnetic measurements receives throughout this work treatment excellent in its way, it demands considerable acquaintance with the subject on the part of the student or reader, and an easy familiarity with off-hand mathematical demonstrations. The concluding chapter on the dimensions of units is particularly complete and instructive, although it can hardly be called a popular description, any more than the remainder of the book, so far as style and language employed are concerned. Several useful tables—in which some typographical errors have been noted—are appended to the end of the volume, among them one giving the numerical values of the virtual resistance of conductors carrying alternating currents, and another giving Matthiessen's constants for correcting the conductivity of metals for temperature. Throughout the text—wherever possible—the solidus notation has been adopted with a view, no doubt, to economizing space.

NEWS AND NOTES.

THE KANSAS CITY CONVENTION.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

ELEVENTH CONVENTION (SIXTH ANNUAL MEETING) HELD AT KANSAS CITY, MO.,
FEBRUARY 11-14, 1890.

The convention assembled at noon February 11, in the Coates Opera House. About 150 members and guests were present.

President E. R. Weeks took the chair and introduced Hon. J. J. Davenport, Mayor of Kansas City, who made an address of welcome.

His Honor said that many of the most important and interesting conventions that had been held in the United States during the year of 1889-90 had met at Kansas City. To none, however, had he extended in behalf of the city a more cordial and heartfelt greeting than on this occasion. "The result of the deliberations of the present convention would be awaited by the whole commercial and scientific world. By means of your marvelous agency you have presented to science wonderful aids, by which she has been able to make visible what has hitherto been invisible, to make audible what has been inaudible, and to discover what has not been dreamed of in the philosophy of mankind."

"As we hear of these mysterious currents measured by amperes, and of the power by which various bodies resist these currents measured by ohms, we seem to be attaining the condition of life of which Mr. Thurston speaks, or that is so cleverly portrayed by Bulwer in his 'Coming Race,' in which all are happy and harmonious, seeming to have reached the millennium, evil being held in bondage by the potent 'vril' wand, which gives to all alike motive, defensive, and creative power, with also the perfect knowledge of how to use it for the greatest and best good of all. Electricity is our magic "vril" wand, and you are teaching us its capabilities."

"We welcome you as true benefactors of mankind, the emancipators of the human race from darkness. What you and those of your profession have accomplished within the past years reflects credit upon your country, borders close upon the miraculous, and entitles you to imperishable honor and renown."

His Honor then briefly recounted some details of the growth of electric light and power as commercial industries, and concluded by saying:—

"To the future we can only look with wondering eyes and bated breath, and to you as the workers of miracles. May your deliberations, gentlemen, while here, be as harmonious as the laws which govern the marvelous and wonderful philosophy of electricity."

President Weeks then addressed the convention as follows:—

PRESIDENT'S ADDRESS.

Gentlemen:—At our first convention, held in February, 1885, there were 87 delegates, full of enthusiasm for the good to be accomplished. I believe they have not been disappointed in the work of this association. As one of the original 87, I point with pride to five years of broadening and harmonizing influence; and I believe that every central station, every factory, every supply company in the country, has felt its impulse toward improvement.

To-day, gentlemen, we number 304, representing not only a wider extent of territory, but all the leading systems of the United States. A more fraternal-spirit prevails between electric light and power men and our elder brothers of the telegraph and telephone interests, a pleasant proof of which has been given by the hearty co-operation of their representatives in this city, in preparing for the entertainment of the convention.

The past work of the association speaks for itself; but our number has so increased, and our sphere of usefulness has so advanced, that we must look for work of a better character than was possible in earlier days, when most of our members were new to the duties which they had undertaken. We now need work of more direct practical value to central station men, and theoretical work of a higher grade than that of the past, good as that has been. With this in view, we have endeavored to prepare a programme of such importance, both practically and theoretically, that you will find it good to be here.

The committee on state and municipal legislation will report the organization of state associations with a view to developing among legislators a full appreciation of the importance and needs of electrical industries, and to present these industries in their true light. The urgent need is for organization along the lines of legislation and popular education. This can be best accomplished by state associations, whose conventions could advantageously take the place of the semi-annual meetings of this association. Ten of these state associations have been formed, and I hope that before the close of this convention, steps will be taken toward the organization of many more.

The increasing interest in railroad work and the immense field for future development in the motor department, will render especially pertinent the discussion by Mr. Sprague, and also the work of the committee on standardization of potential on electric street railways, the report of which will be submitted through its chairman, Mr. Lynch.

As the growth of our industry must be chiefly in the direction of incandescent light and of power, the discussion to be presented by Mr. Field is of the greatest importance, both to central station men, and to all who desire electric service in their homes.

The watch-words of the future are certainly economy of fuel and perfect insulation, and, while there may be improvements in designs for apparatus and in methods and means of distribution, and while we still hope for the direct conversion of the energy of coal, the advance of the immediate future should be in the direction of economizing present waste, rather than in the discovery of new facts or principles. (Applause.) Americans are proverbially prodigal, and there is an absolute and growing need that waste and loss should be arrested. While the demand for the necessary elements is increasing with the population, the supply of many of those elements is steadily diminishing. Messrs. Babcock and Sickles will doubtless point out lines of economy in the department of steam engineering, and Mr. Smith will present for our consideration another phase of the same question—"A Universal System of Central Station Accounts." The many problems arising in the electrical and mechanical departments of the operation of central stations, have left this question to general neglect. But now that we are becoming passably familiar with the tricks of our apparatus, attention is more and more directed to data for comparison, with a view to economic methods.

The topic of the hour is certainly safety. It would seem that, in view of the relatively small number of serious accidents connected with electrical industries, we have grounds for some impatience with the present outcry against electricity as a dangerous servant. It is true, that, compared with those which have accompanied the introduction and use of steam and gas, the number of accidents in the use of electrical apparatus is very small. But in this age comparative rates will not be accepted as answers; the people have a right to demand that devices for public safety keep pace with development in other directions. The papers of Professor Thomson and Messrs. Haskins and Harber, will present this current topic in its various phases. I trust that each speaker will enforce the importance of good construction and maintenance on the part of producers, and proper inspection on the part of the municipality.

It is hoped that the committee on underground conduits and conductors will be able to report some facts regarding the actual operation of high pressure currents underground. Thus far, discussion on this topic abounds in theory and speculation, but contains little experience.

During the past twelve months there has not only been a greatly increasing activity in electrical industries abroad, but many millions of foreign money have been invested in the electrical properties of America. It is worthy of note that our brethren in Great Britain have set the example of adjusting differences amicably instead of carrying litigation to the court of last resort. Such a policy in America would not only have saved hundreds of thousands of dollars now charged to profit and loss, but would have greatly enhanced the value of electrical securities.

The past year has furnished instances in which the value of local electrical properties has been greatly depreciated through the invasion of territory already fully occupied. This policy is short-sighted. Prices in most cities are fair and just both to consumer and producer. To depreciate them will not only ruin the business of pioneer companies who have invested large sums, and borne the brunt of introducing a new and valuable industry, but cannot fail to result in great loss to the invader.

Although electric lighting in this country has seemed to receive a check, a look ahead should not be discouraging. The law that "action and re-action are equal and in opposite directions," applies not only to mechanics, but to public opinion. As America is the birthplace of the commercially successful electric light, and as Americans are the foremost people of the world to recognize improvements, we may well believe that with proper attention on our part to our duties to the public, the present popular and largely sensational agitation against us will give place to a feeling of confidence. In the meantime, let the outcry teach its proper lesson to all engaged in the electrical business. (Applause.)

After the calling of the roll, the report of the treasurer and secretary, Mr. Allan V. Garratt, was read, as follows:—

REPORT OF THE TREASURER AND SECRETARY OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION, DECEMBER 31, 1889.

Balance from account rendered July 31st, 1889, at Niagara Falls	$1,096.93	
Dues from 51 members	1,020.00	
	$2,116.93	
Expenditures as per accompanying vouchers, Nos. 87 to 112, inclusive		$1,506,76
Balance, cash on hand, December 31st, 1889		610.17
		$2,116.93
The indebtedness of the association is an unpaid bill of		259.60
The above expenditure of $1,506.76 for the six months ending December 31, 1889, may be classified as follows :—		
Postage		$48.52
Stationery and printing		143.90
Official stenographer		85.87
Rent of office		50.00
Advertising		46.99
National committee on state and municipal legislation		98.65
Salary of treasurer and secretary		999.96
Expenses not specified above		33.37
		$1,506.76
The total receipts for the year 1889, have been, including the balance from the previous account	$5,845.55	
Total expenses for year of 1889		$5,235.38
Balance, cash on hand, December 31, 1889		610.17
		$5,845.55
The expenditures of the year 1889, may be classified as follows :—		
Old bills incurred previous to 1889		$1,483.82
Salary of secretary and treasurer, 12 months		1,999.92
Clerk hire		40.00
Postage		176.48
Printing and stationery		712.19
Official stenographic reports		246.62
Rent of office		207.50
Advertising in electrical journals		101.99
National committee on state and municipal legislation		98.65
Not otherwise specified above		168.21
		$5,235.38
The net income for 1889 was	$5,545.82	
The running expenses for 1889, were		3,751.56
Excess of net income over running expenses		1,794.26
		$5,545.82

Membership.

Total number of members July 31st, 1889	251
Members added between July 31 and Dec. 31, '89	21
Total	272
Members resigned between Jan. 31 and Dec. 31, '89	13
Making total membership, Dec. 31, 1889	259

It will be noticed that the above reports close December 31, 1889, which is the end of the fiscal year. Since then I have received funds in the shape of dues, and have added a number of new members to the roll of the association.

The secretary's report was accepted.

The secretary then read a number of communications offering courtesies to the convention, including an invitation from the Commercial Club, of Kansas City, to a reception, Tuesday evening, February 11th; a letter from Mr. W. H. Briethaupt, president of the Engineers' Club, of Kansas City, tendering the privileges of their club room to the association during the convention; a communication from Mr. J. H. Veitch, general agent of the Chicago, Milwaukee and St. Paul Railway, inviting the members of the association to visit the health resort of Missouri—Excelsior Springs—and offering a train on Wednesday, the 12th, together with a similar invitation from Mr. Edward Holden, president of the Excelsior Springs Co.; a letter from Mr. William Wiley Smith, secretary and superintendent of the Missouri and Kansas Telephone Co., extending congratulations to the association and offering telephonic facilities.

Letters were also read from the governor of the National Home for Disabled Soldiers, at Leavenworth, Kansas, inviting the association to visit that institution; and from Mr. Geo. W. Warder, tendering to the association, a reception at the Warder Grand Opera House, Friday evening, 14th.

On motion, the above courteous invitations were received with the thanks of the association, and arrangements for their acceptance left in the hands of the president and executive committee.

The president announced that the reception committee invited the delegates and others from a distance, attending the convention, to make the rounds of the city in the afternoon, on the cable cars and elevated railroad.

On motion of Mr. F. Degenhardt a committee was appointed by the president to prepare suitable resolutions touching the death during the year of Mr. C. McIntire and Mr. Miles W. Goodyear. Messrs. Degenhardt, Candee and Garratt were named as such committee.

The president announced that the reception by the Commercial Club, would take place at 8 o'clock in the evening.

The convention then adjourned to meet in Music Hall, at 9 A. M., Wednesday, 12th.

WEDNESDAY, FEBRUARY 12—MORNING SESSION.

The convention was called to order in Music Hall, at 9 A. M., President Weeks in the chair. The secretary read a communication from R. J. McCarty, manager of the Metropolitan Street Railway of Kansas City, extending to the members of the association the privilege of riding free over its lines.

A communication from the Missouri State Association of Architects, in session in Kansas City, was presented, extending to the convention the courtesies of the Association of Architects, and inviting an inspection of the exhibit of architectural drawings.

REPORT OF COMMITTEE ON COPPER DUTIES.

In the absence of Mr. Chas. A. Brown, chairman, Mr. Geo. M. Phelps was called upon to report for the committee appointed at the August convention to memorialize Congress for the abolition of duty on copper.

Mr. Phelps reported that in behalf of the committee he had presented to the House Committee on Ways and Means, at Washington, January 16, the following petition :—

Petition to the Honorable Committee on Ways and Means, House of Representatives, U. S. A.:—

The subscribers were appointed a committee to petition your honorable body for the abolition of duty on copper ingot, plate bars, rod and wire. We represent the National Electric Light Association, a body composed of representatives of electric lighting companies throughout the United States, and also manufacturers of and dealers in electric lighting apparatus and supplies. The resolution appointing this committee was passed without a dissenting vote. We, therefore, have the honor to present this petition, earnestly requesting that the action asked to be taken as a measure, will be approved by the great body of users and manufacturers of copper.

CHARLES A. BROWN,
[Signed] GEORGE M. PHELPS,
J. F. MORRISON.

The presentation of the petition had been accompanied by a brief address to the Committee on Ways and Means, setting forth the reasons which impelled the petition. [The address was printed in the ELECTRICAL ENGINEER for February, page 74.]

After reading the address as part of his report, Mr. Phelps continued :—

The committee has circulated an auxiliary petition in support of that presented in behalf of the association. It has been intended to solicit the signatures of all companies, firms or individuals engaged in electrical industry, and to offer opportunity for signing to all other persons accessible to the committee who are in sympathy with the proposed measure. On the 8th of February, 440 signatures to such auxiliary petitions were forwarded to the Committee on Ways and Means of the House of Representatives. Your committee are still engaged in circulating copies of the auxiliary petition, and hope to collect several hundred more signatures. The committee would earnestly request any members of the association, or others, inclined to sign the petition, who have not received a copy, to address either member of the committee, viz.:—Chas. A. Brown, 227 South Clinton street, Chicago; Geo. M. Phelps, 150 Broadway, New York; J. F. Morrison, 15 South street, Baltimore.

I wish to suggest further that members who feel deeply interested in this matter would, I think, contribute to the success of the petition by addressing communications to their several representatives in the National Congress. It seems somewhat problematical, whether any discussion of the subject of revenue will be permitted to take place on the floor of Congress this session. But, if such a discussion can be brought about there, it is the opinion of your committee that the success of their petition is exceedingly probable. There is practically nothing to be said in favor of retaining the duties on copper. I have not heard a word in defense of them. The only persons who have been at all disinclined to sign the petition, have been those who have said substantially, "Yes, it is all right; the duty on copper ought to go, but we make something else and our friends make something else that is protected by tariff duties, and we do not want this thing stirred up." We feel that the greatest difficulty will be in getting the thing "stirred up." If it can be "stirred up" and brought to the attention of the National Congress on the floors of the House of Representatives, it is my individual opinion, and I think the belief of the rest of the committee, that the copper tariff will not last long.

I am the only member of the committee present. Mr. Brown, the chairman, is unable to attend, and Mr. Morrison, also, is unfortunately prevented from being here. I have made out this report after conference with Mr. Brown, but have not beenable to see Mr. Morrison.

I ought to say further, perhaps, as a matter of record, that there was no appropriation made for the work of this committee. Your committee have expended a considerable sum of money, a good deal of printing and postage being required. In due time, when we are through with our work, we may present, for the information of the association, a record of this matter.

The President—Gentlemen, this subject is a matter of great moment. Aside from its national, I might say international interest, it is a matter that comes right home to every one engaged in electrical business; and it illustrates very nicely the community of interests that prevails, and we should all appreciate and under-

stand it. Whatever affects the manufacturer of electrical apparatus affects the user of that apparatus, and what affects the user of that apparatus must necessarily come right down to the user of the product of that apparatus—the general public.

A motion that the report be received and the committee be continued, was adopted.

REPORT OF COMMITTEE ON UNDERGROUND CONDUITS AND CONDUCTORS.

The secretary read a letter from Mr. Eugene T. Lynch, Jr., chairman, Committee on Underground Conduits and Conductors, stating that the committee had been unable to hold sessions. He suggested that "the convention appoint a committee with the idea of bringing in some of the 'new blood' of the association into this active and interesting field. The experience to be gathered from the operation of such wires as have been buried in New York city (most of which have proved failures up to the present time) can be easily gathered in time to report to the next meeting of the convention."

The report was received, and the committee discharged.

REPORT OF COMMITTEE ON STANDARDIZING OF POTENTIALS.

Mr. T. Carpenter Smith read the following report:—

In behalf of the committee appointed at your last meeting for the standardizing of potentials for electrical apparatus for street railway systems, I would present to the association the following report:—

It was deemed advisable by the members of the committee to send out a circular to all railway companies operating their systems of car lines by electricity notifying them of the appointment of this committee, and asking not only their co-operation, but also drawing their attention to a number of questions that we desired they should reply to. Acting upon this conclusion, the committee drew up and mailed to all these companies the following circular:—

> *Gentlemen:*—At the semi-annual meeting of the National Electric Light Association, held at Niagara Falls, on August 6th, the following resolution was offered and adopted:—
>
> "WHEREAS, It is the belief of the members of this association that the electric motor service upon street railways will require a service of electric current for the motor that will be reliable and constant, and that the various electric light stations are capable of generating and distributing such current,
>
> "*Resolved*. That a committee of three be appointed by the president, who shall endeavor to make such arrangements with the manufacturing companies that they shall adopt some standard potential to be used upon the various railways. The committee also to collect such data regarding the supply of current to railways as may be deemed of interest to the association."
>
> The president appointed Messrs Eugene T. Lynch, Jr., of New York, T. Carpenter Smith, of Philadelphia, and Marsden J. Perry, of Providence, as members of that committee.
>
> It has been thought advisable to collect and compile the opinions and the experiences of such street railways as have adopted electricity as a motor power. Will you, therefore, kindly fill out and answer such of the following questions as you feel you can answer.
>
> 1. What system do you use?
> 2. What proportion of your cars are equipped with motors?
> 3. Do you generate your own electrical power, or are you supplied by an electric light station?
> 4. What proportion does your greatest average horse-power in use bear to the total horse power of engines and boilers which you have installed?
> 5. What is the voltage or pressure of your generators?
> 6. Is there any other railroad in your town using an electric system? If so, what system do they use, and do you know the pressure at which they run?

We have received replies from 85 per cent. of all the electric street railway companies. They have one and all showed every disposition to give us full reports upon the questions that we have asked them, and have stated that they would afford us every facility that lay in their power, and that they desired us to convey to the National Electric Light Association their hearty indorsement of this plan.

We think it advisable to divide our report into three parts:—First, a statement of the conditions under which the various railways have been operating up to the present time; second, the report of your committee upon the arrangements made with the manufacturing companies; third, all of statistics carefully compiled from reports made by some of the most prominent central stations showing the advantages that will accrue to the investor by the combined operation of the electric light and electric street railway interests working under the agreements that have been promised to your committee.

First.—Under the first question we do not desire to give any statements regarding the number of railways that may be operated by any particular company beyond the fact that fully 90 per cent. of all the railways now in successful operation are operated under the systems controlled by the Thomson-Houston and Sprague companies.

In answer to our second question, we find that at least three-fourths of the railways have equipped all their cars with motors, and that the sizes of the motors upon the cars vary from 7½ to 15 h. p.

Third.—Only nine electric light companies have been brave enough to agree to supply the street railway companies with their power, although in nearly every case when the railway was in operation there was at least one central station company who could have contracted to supply the necessary current.

The answers to the fourth question give to your committee the information that will prove of value to the association. In all railways operating over 15 cars, only one-third of the total horse-power with which the plant has been equipped, has ever been called for at one time. On all roads operating between 5 and 15 cars the greatest average load has not reached 50 per cent. of the total horse-power, and upon smaller roads the average load has varied from 50 to 80 per cent. of the total horse-power. All roads that have met with heavy grades have raised the average very considerably.

We find that the potential varies from 220 to 800 volts. The greater number of companies, however, report using a potential between 450 and 550 volts.

Our sixth question was directed partly as a check upon our being furnished correct information upon the names and locality of the various roads, but mainly to ascertain whether an opportunity was afforded to operate several street railway companies from the same central station plant.

The answers to this have been many and curious. In some cases they have disowned all knowledge of the existence of any other company, and in nearly every case they seem to be imbued with the rivalry quarrels or misunderstandings of the various patent or manufacturing companies whose apparatus they are using. They agree, however, that they would be willing to use the power supplied to them from some central station, provided that they be assured by the company who equipped their road that the potential of quantity of current used would not be detrimental to their apparatus.

Copies of the circulars, together with a letter explaining more fully the plan suggested by your committee were sent to all the manufacturing companies. They were also requested to furnish the committee with a list of the particular railways operating under their systems. After much correspondence and many personal interviews, your committee would announce that they have written authority from both the Thomson-Houston and Sprague street railway companies that they will agree hereafter to use a standard potential of 500 volts upon all electric street railway equipments that do not require any special apparatus for their successful operation.

In recommending electric light companies to add to their regular central station business the business of furnishing power to street railroads, we wish it fully understood that we do not base any hopes of profits to be made upon the old-time idea that the same machinery can be used for furnishing light at night and power in the daytime. This specious argument has led many companies into large expenditures for motors, etc., and they have discovered later that it costs very nearly twice as much money to run the same machinery night and day as to run it at night alone, and that it pays better in the long run to have an entirely different class of apparatus to produce light and power.

The true direction from which returns may be expected in the massing in large stations of the generation of electricity for both light and power, is found in the fact that an electric light station to be sure of a continuous running, requires a reserve of from 15 to 25 per cent. of its average load in boilers, engines and dynamos; the per cent. being larger in small stations and diminishing as the station increases in size.

This same reserve in capacity is required for the power station, but on street car work in most of the stations hitherto installed, this percentage runs very much higher, being from 50 to 80 per cent. It will be manifest to everyone on a little reflection, that a station which is generating current for two street cars, is compelled to have power enough provided to allow of the throwing on at the same instant of both these cars, that is to say, generating capacity of fully twice the average amount of power, or 100 per cent. reserve; as more cars are added, the chance of any particular number being thrown on at one time becomes less and less, until in a station operating 200 cars, a single spare generator to take the place of any one which might be disabled, would probably be all the reserve needed. This feature is shown very clearly in the running of the ordinary three-wire electric station, where when the total load is light a few lights thrown off or on either side will make a big difference in the balance, but as the total load increases, the number of lamps thrown off or on either side at any one instant is so small a percentage of the total load that the station needs practically no balancing. Now if in any station supplying electricity for all purposes in a town, we have say 25 per cent. reserve in boilers, and 25 per cent. reserve in steam engines in excess of the average load, we shall only require to place 25 per cent. reserve, each, on electric light dynamos and power generators to have practically the same result, as though we had two complete and separate stations for electric light and for electric power, each with its proper reserve of 25 per cent. extra in engines and boilers and dynamos.

Another important point to be considered, and one well worthy of consideration by electric light stations, is, that in many cases they could furnish this current delivered at the walls of their stations; that is, the car company will take care of its overhead lines and connections, and the electric light companies be paid a rental simply for the electricity delivered to the car companies' lines.

As an instance of what may be done in increasing the output of a station, without corresponding increase in expenses, we quote the case of a small station, which, as nearly as can be determined from results, shows the following condition of affairs :—

The station increased its business in 1889 over 1888, 23 per cent., and in the same time the total expenses including the extra line work and distribution expenses 10 per cent., which 10 per cent. meant 10 per cent. increase in running expenses and 10 per cent. in fixed expenses. The company contemplates a further increase of 27 per cent. on the same basis ; this increase, however, being for power furnished alone, without any line work involved ; the most careful calculation shows that this will only increase the present running expenses 10 per cent., without increasing the fixed charges at all.

In 1888 the proportion of fixed charges to running expenses were 25 per cent. and 75 per cent. respectively of the total expenses. In 1889 this same proportion held good, each having been increased 10 per cent., as above stated, and the total expenses having increased the same amount. The further expected increase being 10 per cent. of 75 per cent: will mean an increase in the total expenses in 1890 over 1888 of 17½ per cent., while in the same time the total output of the station, and consequent gross receipts, will have increased 50 per cent.

These figures are all taken from the case of a small station, with a total output of some 350 h. p. and a fresh increase in this station (above this point) will result in an entirely different condition of affairs, so that a readjustment will take place in the proportion of fixed expenses and running expenses. We therefore present the report of another station which is operating 1,200 h. p., in which the total operating expenses are divided into 80 per cent. running and 20 per cent. fixed. On increasing the station to an output of 1,800 h. p., the increase to be entirely in the furnishing of power, the increase on total operating expenses would be about 14 per cent., and the ratios of fixed and running expenses would be as 15 per cent. and 85 per cent.

The report of another large central station operating at least 2,500 h. p., has been divided somewhat differently. The fixed charges are 14 per cent. of the total expenditures. All labor and pay-rolls amount to 41 per cent., and all material such as coal, carbons, lamps, wire, oil, etc., amount to 45 per cent.

Taking in account all their past calculations and experiences, they are very confident that they can operate at least double their present output, be it light or power at one-fifth more for fixed charges, one-third more for all labor and pay-rolls and say three-fourths more to their present material item, making a total additional charge of say 50 per cent. upon their present expenditures and giving them in return at least double the gross income. As stated before, it will not be found advisable to calculate upon using the same engine, boiler, and dynamo power for the double service for lighting at night and power during the daytime, except, of course, in some few isolated cases.

The great saving for the central station company lies in the reducing in labor and fixed charges, and also that the reserve power for one will suffice for the other. Your committee feel that a great step has been taken in the right direction in securing the indorsement and co-operation of the largest and leading companies, and they would suggest to the association that some measures be taken to secure from the stationary motor companies the adoption of some standard potentials for their use upon constant potential circuits.

REPORT OF THE COMMITTEE ON HARMONIZING INSURANCE AND ELECTRIC LIGHTING INTERESTS.

Mr. P. H. Alexander read the following report :—

The committee on harmonizing the insurance and electric lighting interests was continued at your session, held at Niagara Falls last August, and requested to confer once more with the fire underwriters regarding the best means of preventing fires from electricity, and to try and bring about a reduction of insurance on the buildings lighted by electricity. The committee has had many sessions, and a great deal of correspondence with fire underwriters, and can only reiterate the recommendation made at the last meeting of this convention regarding the desirability of examining and licensing men employed in electric lighting, and would further recommend all electric light companies to contribute toward the remuneration of several expert electrical engineers in different parts of the United States, who should instruct special agents or inspectors of insurance companies in the necessary knowledge to discern between good and bad electrical installation. The committee thinks that special agents and inspectors of insurance companies ought to qualify themselves in inspecting electrical installation, as far as fire is concerned, the same as they qualify themselves in inspecting other appliances put up in buildings, and judge of their relation to fire hazards. The committee realizes that as long as inspectors are employed at the expense of the electric light companies, underwriters will take no pains to acquire for themselves the necessary knowledge to inspect such risks. The committee would, therefore, recommend to electric lighting companies the appointment of an instructor to special agents for a period not exceeding one year, feeling certain within that time every special agent and inspector of fire risks could acquire all the necessary knowledge to enable him to judge of electrical installation as far as it applies to fire hazards. The committee has communicated this, its ideas, to underwriters' associations and insurance boards, but must confess that it has not met with the favorable responses to this proposition that it anticipated; however, the insurance interests seem to be willing to take some steps to bring about the harmonious relations so much desired. Your committee was also instructed to report upon the advisability and feasibility of a mutual insurance company for insuring central stations. A plan was proposed by S. E. Barton, and Captain William Brophy, both of them well known to you, for the establishment of such a mutual insurance company, a prospectus of which is filed herewith, and has been forwarded to the members of this association. The committee after carefully considering the plan of operation as prepared by these gentlemen, has unanimously indorsed their ideas, as have a great many central station men of note, members of this association, as well as of the association of Edison Illuminating companies. The plan proposed will not only reduce the cost of insurance, but will aid in perfecting the construction of central stations; and by frequent inspections will aid the managers of such stations in the knowledge of modern appliances. Your committee would be glad to have this matter freely discussed here to-day to see if the project is not worthy of the official indorsement of the National Electric Light Association.

DISCUSSION ON INSURANCE REPORT.

Mr. George Cutter, of Chicago—We find constantly people who want their work done according to insurance rules. We have no uniform insurance rules; one engineer works upon one line of rules, and another upon a different line. I feel that if a committee composed of electric light and insurance men would work together to outline a national line of rules for electric installations all over the country, we would all be benefited by it. The necessities of the case have given rise to a lot of consulting engineers throughout the west. The uncertainty among purchasers of electric light plants, from the many contradictory statements made by salesmen, has made a demand for consulting engineers, and this is being filled in a very unsatisfactory manner. These men are opening offices and traveling about as consulting engineers, and among them are many who have no practical experience whatever in putting in installations. I feel that a superintendent of installation should pass an examination. This would sift out these so-called electrical engineers, whose knowledge extends, perhaps, to the putting up of a vibrating bell, and who know absolutely nothing about electric light plants. The inspection of an electric light plant requires experience in installing and handling apparatus. I believe in the value of a standing committee of electric light and insurance people working in harmony, to keep pace with the growth of our industry, so that we may know the best method of installation. New ideas are advanced constantly, with a diversity of opinion as to the correct use and installation of apparatus. The result of the work of the proposed committee, would be that the public would gain that confidence in electric lighting which it deserves, and the purchaser of electric light apparatus would have information as to what good installation is.

Mr. T. Carpenter Smith, of Philadelphia—I am much in favor of such a committee as has been recommended. I represent a company in what is usually called a slow-going town, but we have made some progress. We have an insurance inspector, who has taken an original course. He absolutely refuses to lay down any rules for wiring, on the ground that just as soon as an absolute rule is made, just so soon will be found the means to evade it. He has also been opposed to the licensing of wiremen, on the ground that while you may very easily control by a license system the extent of a man's knowledge, you cannot control his trustworthiness. We have men doing wiring as contractors in Philadelphia who can pass any examination. Yet these men will deliberately splice underwriters' wire on the inside of a building, and splice waterproof wire on the end of it where it comes out, and will wrap tin-foil around the splice, so that it looks as if it were soldered. Now, no licensing system will control men like that. Common sense is more important than electrical knowledge in wiring, especially about central stations. In the early history of the art underwriters' wire was cleated to the floor and run through a house without any rubber around it, and it was thought good enough. Then we had a scare about the water-proof business, and everybody lumbered up with rubber-covered wire and other things. Then we got to running rubber-covered wire on glass insulators, and thought that was just the thing ; but a day came when we found that the rubber cover carried the flame better than the electricity did. Now we have got down to porcelain and glass insulators. We have begun to find that our old despised friend, underwriters' wire, is not a bad thing to go through a building, because while it may get wet, it will not carry the flame. I think 90 per cent. of the little troubles occurring in Philadelphia come from the flexible cord which has been handled until all the strands are broken. All at once a little blaze is discovered in the ceiling. In Philadelphia a scheme has been formulated which has the germs of good in it. The lighting companies cannot compel a customer to have his building wired properly.

There is no question but that the insurance people can compel a customer to do anything. The worst class of customer we have to deal with is the very one who is scared the most about having insurance taken off his building, and a mere suggestion or hint from his insurance company that it will not continue his policy, will bring him to terms in a moment. We should attempt to throw the onus of all compulsory work on the insurance companies.

We are talking of an arrangement whereby the electric light companies are to pay an annual sum to the insurance companies for every arc light installed, and for every incandescent light installed. This is to apply to the maintenance of a staff of skilled inspectors, who shall not merely inspect all new work, but shall periodically inspect all work already installed, so that any changes may be examined, and any man who is found sticking 50-candle lamps on a wire that was meant for 10's can be detected. This practice will be stopped by a power that is greater than that of the electric light men—the threat of withdrawing insurance. The matter comes to this:—That a certain sum has to be paid every year for skilled supervision and inspection of all new work and all work already installed, the cost of this inspection to be divided pro rata among every user of incandescent and arc lamps, the only difference being in the case of people who are supplied from central stations, that the central station shall bear that expense. I think that the cost of such a system would be ten times paid to an electric lighting company every year, in the satisfaction they would have of knowing that somebody else was responsible for the condition of their numerous wires. The gas companies started, just as we have, by piping people's buildings and doing everything of that kind. Gradually they cut off these luxuries, and now they have got down to delivering gas at the customer's premises. They put their meter in and are responsible for it, and beyond that they are not responsible; and the electric lighting company must get there too just as quickly as possible.

Mr. M. J. Francisco, Rutland, Vt.—Mr. Smith has overlooked the fact that in New England we have an association of the very kind that he desires in Philadelphia. It is the New England Electric Exchange; and we have also the New England Insurance Exchange. The two are working together as one body, practically; that is, the orders of one go into the other and they are enforced by one organization.

If they have proper men in Philadelphia to examine wiring, I do not think they will find much tin-foil in place of solder. At least if they ever try that with Captain Brophy as inspector, they will get terribly left. He is the inspector for New England. But there, we have this plan: These men are licensed. One of the conditions that has to be considered is the moral character of the man. That man must have a record; he must have a standing, or he cannot procure a license. All buildings have got to be wired in accordance with the rules of the Insurance Exchange. After they are wired, the electric lighting company invites the exchange to send its inspector. If they are in accordance with the rules of the exchange, as well as of the company, they are passed; if they are not, they must be taken out and be put in as they should be. The moment owners refuse to do that, not only do they receive the electric lighting company's order to discontinue the current, but they have the Insurance Exchange to deal with, which cancels every policy on the property. That is the basis on which all this business should be carried out through the whole United States.

I have always been a little skeptical about mutual insurance, but in the scheme proposed in this association and practically indorsed, we shall have at the head two men who have had as long and as varied experience probably as any men in the United States. With their experience and knowledge at the head, I consider that we have a plan that we can all heartily indorse, and one which will give us insurance at its actual cost. In the last year I have received 150, if not 200 letters, asking, "Why cannot we get our property insured, and how can we arrange our stations so we can insure them?" I have had other letters saying, "The insurance companies are charging us five per cent. on our station." Of course there is some reason for that; companies do not do such a thing unless there is a reason; but in many instances, it is because the companies do not understand the rules and principles for arranging stations. The insurance companies, in a large number of cases, have inspectors of insurance risks, who know little or nothing about the electrical part. We want inspectors who thoroughly understand the electrical part of the risk. I am heartily in accord with the movement before us, and I trust every station man will investigate the matter and take hold of the subject in the proper spirit.

A national exchange would be too extended to be practical. We have now the New England Exchange, then we will take in the middle states, then the western states, the southern states, so as to make a department each by itself, the same as the insurance companies do at the present time. Divide up, but have all under one head in the national association.

Mr. J. E. Lockwood, of Detroit—This, it seems to me, is the proper time for the National Electric Light Association to make use of the state associations for the purpose of getting direct communication with each local organization in the country. The matter depends, I think, upon the organization of the electric lighting interest in each state and city. As there are electric light interests in each city, so also are there companies in each city, and the national association is represented in the local organization. I think if this committee is formed, its function could be more properly performed by formulating the ideas derived from men of experience all over the United States, and which information could be gathered and furnished by the state associations. Then let each state association apply in its own state this information and instruct all of the electric lighting companies, and the insurance men throughout the state, with the proper rules for wiring; and then through its own members, residents of every city of the state where there are electric light plants, see that these rules are carried out. In Detroit we have had the same thing to look out for. We have just formed a state association. There are probably at present not less than a half dozen different companies doing wiring of buildings, in one of which that I know of, the wires are being concealed within the mortar; and for a single light they are putting in No. 20 wire, which I know is smaller than is thought proper. We have fortunately not had a great many fires; but we have had our attention called to these facts, and the number of accidents in other cities which have been published in the papers. Our state association intends making its best effort to investigate thoroughly this matter of wiring, and to formulate rules and endeavor to carry out those rules. We shall look over the work of the state and see that no work is done in future that will not be strictly good electrical work. I trust that when this committee is formed that it will carry out this work in such a manner as to make the state associations the mediums of communication between the National Electric Light Association and the people whom we are going to reach.

Mr. T. Carpenter Smith—I do not want Mr. Francisco to suppose for an instant that we allow such a state of things as I spoke of to exist when we know of it. The point I wanted to make was that the moral character of the wire man was only good when you know it. We have had a good many bank presidents and cashiers who were very worthy, responsible and trusty men—until they went to Canada. And it is the same way with the wire man. He is all right until you catch him. And in order to catch a man's moral character you have got to have some way to defend yourself from that man after you have found him out. Now, as I say, our record in Philadelphia on the question of fires shows we have a good system of inspection there; that is, that the work has been well done. But where a wire man is at work on the sixth or seventh floor of a building and he has got one more joint to solder, it is an awful temptation to that man to twist a little copper wire and let that slide in a place where it will never be opened. You take a building with 3,000 lights in it, and there are a good many of such, where every foot of wire is concealed, you would have to put half a dozen inspectors on that one building, the whole time the work was being done to know that every joint was soldered. I am strongly in favor of a committee of this kind; but the point I want to make is, that we must look more to getting honest work, than to laying down rules that can be evaded. You must make it a question of principle. I would like to see some system devised which would be practicable, and leave the question of rules as much in the background as possible.

In stations there is no necessity for concealing work of any kind. The rules that govern ordinary fire risks, I think apply more to central stations than to any other buildings. I think there is infinitely more danger in the electric lighting stations from the boilers, engines and heating apparatus, than from the electric lighting wires, except, of course, the habit of throwing water on machinery that gets heated up, and I guess none of us would think of that, although we have heard of such things being done.

Mr. Cutter, of Chicago—About four years ago, I think, the New England Exchange was started. I like the idea of it. But must we wait four or five years for an exchange in the west, and then another lapse of time for one still further west, and then finally join them in the national exchange? Can we not start the ball rolling to-day and from the National Electric Light Association have a national exchange that will establish the necessary organization? We do not want to wait longer in the west for the good results that you are getting in the east. We want if possible to start some sort of bureau or exchange that will be a national affair, that will be the centre of information for the best class of work and the best policy to be pursued in putting in our plants. And we want, if posssble, to start from this association and at this meeting. The New England Exchange has a sound policy. I feel that if the wire men of experience and the men who are working on important parts of construction are required to have a certificate from certain associations, and that when any wire man carrying such a certificate is caught leaving an unsoldered joint, or covering a joint with tinfoil, he must lose his certificate, that is something more than a moral power. It is bread and butter for the next week or six months, and he will not want to lose that certificate. We want this committee to be appointed on a basis, if possible, for prompt action, to organize the National Electric Light Exchange, if you want to call it so.

Mr. De Camp—As Mr. Cutter just remarked very pertinently, we do not want to wait four or five years to educate up a corps of competent construction men. Let this very admirable committee devote its attention to the education of a corps of first-class inspectors from among the construction men, with a view to their employment by the insurance companies. The consumer will give his inside wiring to the lowest bidder ninety-nine times in a hundred. He has no means of knowing whether it is a proper piece of work or not, but he will believe the insurance men. He has an interest in his insurance. If it is a question whether he will dispense with insurance or dispense with our light, he will dispense with the light every time; but if it is generally known that the insurance company with whom he is doing business has a competent inspector, then that contractor must do that work under an educated and thoroughly competent inspector.

I suppose there are fifty, maybe a hundred, so-called construction companies in the city of Philadelphia to-day, and when we have occasion to discharge a workman the chances are two to one that he will turn up in time as an electrical engineer. Without a dollar of capital they will take a bid on a contract amounting to a thousand dollars. They manage in some way to get their goods; they will say they have such a contract, and want $400 or $500 worth of goods and cannot pay for them until they finish the job, and when they get paid for it they will turn the money over. Now, if those men are watched and cannot get their work passed, and they cannot pay their bills, their creditors will find that out as soon as anybody, and they must gradually drop out of the field. We have in Philadelphia one inspector who has done all the good work that has been done there. He works by common sense, and that he is pretty near right I do not think requires any better proof than the fact of the little trouble we have had up to this time.

Mr. Marsden J. Perry, of Providence, R. I.—One very strong point has been brought out by Mr. Smith, and that is, that the combined insurance interest, rich in its aggregate capital of hundreds of millions of dollars, requires to have the hat passed around to the tune of two cents to each lamp; that is a fact I am very glad to learn, and I shall take it back to my people with a great deal of satisfaction. You appointed a committee a year ago, of which I had the honor to be a member. Its report has been before you for discussion. If we go on forming exchanges and working down through school districts and up through counties and states and finally have this grand national insurance exchange, we shall have a grand institution; but what will become of the wiring and the general progress of the business while we are waiting for that consummation? If one year ago, when this committee was appointed, you had simply recommended to the insurance companies that they send their inspectors to first-class, reputable electrical engineers, and they had spent one week in conference with those gentlemen inspecting the installations in almost any town, at the end of that time or a fortnight they would have had sufficient knowledge to enable them to inspect decently almost any ordinary installation, and the whole thing would have been settled. That is where it must come finally, and we might as well begin at that point as to spend a year getting there. There exists no necessity whatever for this grand and intricate organization. Why should our business be made a special exemption from the ordinary routine by which such matters are accomplished? There is no mystery about the carrying capacity of a wire. For one cent you can buy a set of tables which any mechanical engineer will endorse as being perfectly safe to follow. It is a very simple matter, and it is a matter that rests entirely with the insurance company finally to say that they will or will not accept the installation. The question of poor workmanship will be settled by that very definitely. When a man or a construction company has made a bid so low that it is necessary to put in inferior work to protect against absolute loss, and the work has been rejected by the insurance inspector, and the man with whom he has contracted has thereby been given a just reason for refusing to pay the bill, and he is obliged to reconstruct it and make it meet the demands of safety, there will be no trouble; he will not repeat the dose. I do not believe that there is the slightest necessity for going into this work at all. I think that this convention should carry out to a great extent what we have recommended in the reports. The insurance inspector who steps into a building and is competent to inspect everything in it except electric wires, should make himself competent to inspect that risk and accept or reject it for cause.

Mr. E. A. Armstrong, of Camden, N. J.—I do not believe that this convention ought to employ an instructor of insurance inspectors. If we are to go into the business of employing schoolmasters for the populace, the first thing we will have to do is to employ a schoolmaster to go to Ohio. I saw in a paper here that a member of the legislature of that state had introduced a bill requiring all the dangerous electric wires to be buried throughout the whole state, and yet confessed in introducing the bill that he had never seen an electric light wire or an electric light until four weeks ago when he went to Columbus to be sworn in as a member of the legislature. I am sorry to have to admit it, for the sake of the argument, and I trust it may not be held against me, but I have been a member of a state legislature and I know something of the wisdom and intelligence of state legislatures, and if it is proposed by the aggregation of the electric light companies of the United States to endeavor to instruct men in what they ought to know, and in what they pretend that they are competent to do, we might as well surrender to them at once our whole plant and go out of the business. The insurance companies are to insure us, and as Mr. Smith well said, "I think they will very readily and speedily find means to ascertain whether or not the work that is done is properly done." I happened to be the president of a company that had constructed a hotel within about thirty miles of Philadelphia. We gave the contract to the lowest bidder, and so we ought to do. The insurance companies sent their inspector to see the work, and the work was condemned. We have not paid for it. We immediately notified him that we would not accept his work and gave the contract to some one else; the insurance companies did that. We do not propose paying for this inspection; they are the ones to do the inspection and tell us whether the work is done satisfactorily or not. I am president of an electric light company. I do not propose to have my company either inspect or pay for the inspection of buildings; we will furnish them the light; they are to ascertain for themselves, or the people who underwrite them, whether the work has been done properly. Let the insurance companies look to that.

Now, as to the recommendation of mutual insurance companies for electric lighting, I should be very sorry to see this convention advocate the establishment of a company to manufacture wires or a company to manufacture dynamos or a company to manufacture lamps or switches, because, as an electric light company's officer, I want to get the best at the cheapest possible cost to my company, and I do not propose to start something myself or in connection with other electric light men to beat down prices. I have one branch of business, and while mutual insurance companies are a great benefit sometimes, yet I feel that this convention would be making almost a fatal mistake if it adopted this report as it stands, recommending the institution of a mutual insurance company. Let us see ourselves that our work so far as our plant is concerned, is done with regard to our own safety and then we may rest assured, as Mr. Perry said, that this great aggregation of millions of capital in the insurance companies will furnish to us insurance and underwrite us much cheaper than we can do it ourselves; so do not let us adopt that part of the report.

Mr. Perry, of Providence—My remark relating to insurance companies applies specifically to wiring done outside of our stations; but I do unreservedly want to put myself on record as indorsing the plan for a mutual insurance company for central stations.

Mr. Alexander—New Jersey, as you all know, is different from any other state in the country, and therefore the insurance men there may be entirely different from the insurance men in other states; but we in New England have found that insurance men refuse to insure us. Now, what are you going to do about it? Are you going to go without insurance because you think they are wronging you? No. They do not know anything about electric light. I do not blame them. They think it is dangerous. They say, "We are writing an ill-understood risk, and we ought not to be put to the expense of providing a competent authority to ascertain how to estimate this new risk." They talk very fairly about it. When they find the risk a good one, they reduce the rate, and to-day every building in Taunton that is lighted by electricity has a reduction of ten cents on its insurance rates. I believe the money paid by the lighting companies is flowing back into their pockets; their business has increased rapidly on account of the good inspection.

Mr. S. E. Barton, of Boston—I was much interested in the remark of the gentleman from New Jersey, but he evidently does not know what is going on in the United States. I have been an insurance inspector myself for fifteen years. I would not consider myself competent to be an inspector to-day; I would not consider myself an insurance inspector in all that that term implies if I did not consider myself competent to inspect an electrical installation as well as a gas installation, and that is the very point that we are hammering at in the report of this committee. Now we have had the industry of electrical lighting going on in this country ten years or more, and to-day out of nearly one thousand inspectors employed by insurance companies in this country I do not believe you will find two of them that pretend to know anything about the inspection of electrical apparatus. Why is this? Simply because they have let that alone as a subject too deep for them and left it to work out its own salvation, and in letting it work out its own salvation you have made the mistake. Installations all over the country abound with errors that are incident to first construction; things that could not be avoided, but things that can be avoided and remedied in the future. Good inspection you say is what you want; you don't want to pay for it, but you cannot get anything in this beloved country unless you pay for it, or give an equivalent in some way. Now we have examined this matter, and we have taken the position that the man to inspect the insurance business is the insurance inspector who inspects every other hazard. He is not competent to do it to-day. You yourselves who have been in the business all these years know that he cannot be competent to do it without more instruction. He cannot qualify himself in a day; he cannot qualify himself in a year without an instructor. Now we have taken the stand and hold to the proposition that it is wise for the electric lighting people, not this association, but the electric lighting people throughout the country, to put their hands into their pockets and say to the insurance fraternity, "We will provide the instructors, not to instruct the people of the country *and* the legislators—that would be a hopeless task,—but to instruct the insurance inspectors in what is necessary to qualify them in their inspection." By the appointment of a sufficient number of instructors you could furnish object lessons to these insurance inspectors, show them what is necessary when they have to discriminate between good and bad work by showing the good and the bad to them. This committee was appointed, not to point out what ought to be done, or what are the rights of the electrical people and what are the duties of the insurance people, but its very name tells what it is for; it is to harmonize the interests of the insurance and the electric lighting people; and the way we believe they can be harmonized is by conceding on the part of the electric lighting people in the first place so many dollars and cents, to be paid out by the insurance people to the end that at a given time, giving them fair notice in the beginning, they are expected to have their men qualified and competent to do it, and take my word for it they will be so. In Philadelphia, as Mr. Smith says, they are doing good work, but they are doing simply what we have been doing in New England for years, and they are reaping the benefits of it. They are getting lower rates of insurance on properties lighted exclusively by electric lights than by any other class, and the insurance side is losing nothing by it. From my standpoint, as an insurance man, I wish every other kind of illumination was driven out, and that electric lighting was the only thing used. We would have a great many less fires. Now, then, I want to say a few words in relation to the project of an electrical mutual insurance company. I have had it in my mind for some time. If you will call to your minds one year ago, at Chicago, in speaking upon electrical lighting stations as fire hazards, I said that I believed the establishment ultimately of an electrical mutual insurance company, or something of that sort, would be the only solution to the question of insurance on central stations. I believe it more fully to-day. And I also said at that time that I believed that those few companies who are doing business in insuring electric lighting stations to-day, even in their deplorable condition, are making money. *Now* I know they are. It is not intended to antagonize the stock interest at all, but on the contrary to take in with it all those who want to come. Eight of them have manifested that desire, and a representation of the largest American company stated to me recently that it had been insuring electric light plants, central stations, for several years at nothing less than two per cent. They have made that the minimum rate and they have taken almost anything at two per cent., and have made money out of it. They have kept it to themselves; they now come forward and say they do not want to lose that class of business, but we want to come into this plan and take a share of it. A representative of one of the smallest companies in the country, a company which started a few years ago, told me that it took electric lighting stations simply because it wanted business and could not get anything else, and within two weeks he told me that its premiums in two years were over $60,000 and their losses less than $300 on electric lighting central stations.

I want to say a few words in relation to the examination and licensing of men employed in electric lighting installations, the work being done by the New England Electric Exchange. I cannot agree with my friend Mr. Smith, that that method does not give a guaranty of the character of the man. On the other hand, that is one of the important features of it. It examines him technically first; it then considers his moral aspect, and not a license is issued until it has been laid before and countersigned by the man who knows him personally and knows his habits and everything pertaining to him better than anybody else, and that is the inspector of the New England Insurance Exchange. Every license has to go before him, and receive his countersign, and thereby the exchange has the guaranty that that man is all right in every respect. I know it is so, because I know that more than one man has not received a license simply because he did not meet the requirements in that one particular phase while he did meet them in other points. Now, Mr. Smith says we do not need rules for the installation of electric lighting apparatus. I can hardly agree with him there. I myself feel that the rules that we have in New England are on the wrong tack, that if those rules were turned around, and instead of saying what *should* be done in the line of safety, they said, what should *not* be done, it would be more in accordance with my ideas. But we could not start that way. We did not know in the beginning what should not be done. We knew in a crude way what should be done; we have gone on, and from time to time, through experience, we have added to those rules until they are complicated, and cover a great deal, not of ground, but of paper, and I believe, as Mr. Cutter said in the beginning, that it would be to the advantage of the electric lighting industry all over the country, if some sort of committee could be formed to draft a set of rules. It could be made a standing committee whose duty it should be to consider and revise the rules from time to time; then we would have some rules that would obtain not only in New England, but in California, and even in Chicago. When we first started the method of examination in New England we had a different inspector for each locality, one at Boston, and one at Portland, New Haven, Springfield and Providence. What was the result? A party installing a plant in Maine was subjected to one set of rules; when he went to New Haven or Providence or anywhere else, he had to conform to a different set of rules. We ought to have some general rules, so that the party installing in New England would meet the same rules when he went to any other part of the country. I would like to see a committee appointed for that purpose, and I would like to have a good part of that committee made up of insurance men, who are the only men who can enforce any rules you make. I would have a certain number of practical electrical experts on the committee, and these men could be selected—one or two by this association, and one or two by your sister Edison association—and let the committee be large enough to cover the entire country and small enough not to be cumbersome, and let it govern the question of rules and let those rules be condensed and solidified and brought right down to what is useful for safety, and then have the rules so framed that the insurance inspector—who can tell you all about everything except electricity—can understand them. Going back to the subject of mutual insurance, I want to impress upon you the importance of the fact that the inspectors of your mutual insurance company will be excellently qualified to give valuable ideas to the insurance companies. The company will break down all the barriers of prejudice; it will show to the country that you are not afraid to insure your own plants, that they are not those terribly hazardous fire generating establishments that they are commonly understood to be. I hope that the recommendations of the committee will prevail.

President Weeks—We have with us Captain Brophy, of Boston, of whom we have all heard much and from whom I am quite certain we would like to hear more on this occasion.

Captain William Brophy—I am pleased, as one who has no pecuniary interest in any electric lighting company, to have the privilege of saying a few words. I began with the New England Exchange four years ago to examine the work done by electrical people, and am happy to say that I have had the hearty co-operation of all engaged in that business. The insurance people were ignorant of this new element introduced into buildings, and naturally were wary of it; they felt that it was not their duty to maintain this inspection, as all their risks were insured and rated before electric light was introduced. So they made arrangements with the electric light companies to bear a large portion of that expense. To-day more than one of them have testified to me that the expenditure thus made has been returned a hundred fold. We have been exempt from injury to life and person in a remarkable degree. The few accidents that occurred were purely on account of the negligence and recklessness of the unfortunate victims. Our losses from fire have been so small that they are hardly worth noting. I wish to state here emphatically that the report made by the worthy fire marshal of the city of Boston to the board of aldermen that in his belief the disastrous fire of Thanksgiving Day was due to electric wires, was made without due deliberation and with a wonderful lack of necessary information. Anyone who knows anything about the condition of affairs there, must know that that was not the cause of that fire. I certainly do, and if I had any respect for the electrical knowledge of the worthy fire marshal of the city of Boston previous to his report, I have since lost it. We have had since the organization of the exchange a set of men employed in construction work that in point of intelligence and knowledge of their business cannot be excelled in this country. The time is fast approaching when the duties of the inspector must cease in New England unless he wishes to be a pensioner upon the bounty of the electric light fraternity, and he has not reached that age as yet. This is owing to the hearty co-operation of the men engaged in the electric lighting business in New England. As I have stated to our executive board only a day or two before I came here, the work is now done so much better than when we began, that in many cases the duty of the inspector is simply a matter of routine; we have arrived at that happy stage by a rigorous inspection, by rejecting every piece of poor work that we could find, by impressing on the minds of those engaged in construction work the futility of attempting to palm off anything that was not first-class, and in all this work we have not been obstructed in the least by the men most interested—the electric light companies and construction companies. There is a prejudice in the minds of the people that never should exist. Many people believe that death is present in every foot of electric wire. Many people believe that when it is introduced into their buildings their property is liable at any time to be destroyed by fire. There is no just reason why this should be believed. The men engaged in the electric lighting business in New England are as honest and as unwilling to hazard the lives and property of any of their customers as they would be to imperil their own, and the feeling in the minds of the public has been created largely by the sensational press. It is unjust that electric light men should be subjected to such an outrageous raid on their business by the press of this country, by men who write articles, but do not know the technical difference between a wheelbarrow and a dynamo.

Mr. T. C. Smith said that many fires are attributed at once to electric lighting, when if the building had been properly inspected the accident would not have occurred. In one case Mr. McDavitt, of Philadelphia, went into a mill the proprietor of which was in the state of mind that the public generally is, and thought he was liable to burn out at any moment. The first thing that he saw was a large bundle of greasy waste, and he said, "You are in more danger from that pile of waste in one day than you would be from electric lights in ten years."

Mr. E. H. Williams, of Cincinnati, spoke in favor of the report of the committee from the point of view of a shareholder in insurance companies. He thought highly of the proposal to found a mutual electric insurance company.

The organization of state associations seemed to be in the direction of harmonizing insurance and electric interests. The committee should have before them, also, the question of deciding upon the value of the various safety devices now offered. We want rules; but they should be as simple as possible and be clearly understood. His companies would be glad to aid in the organization of the electrical mutual. They will furnish the result of their inspections and will endeavor to ascertain the dangers, and will expect electric light men to assist in avoiding those dangers.

The report of the committee was adopted.

The secretary then read a paper on "Construction of Central Stations," by Mr. C. J. H. Woodbury. (See page 98.)

DISCUSSION OF MR. WOODBURY'S PAPER.

Mr. M. J. Perry, of Providence, R. I. — I think I speak advisedly when I say that almost every central station man throughout the country finding his station too small has enlarged it to meet the requirements of all time, got it not quite completed, and then found it was still too small. I think we have rebuilt three times but the last time we determined to settle that matter for a considerable period, so we bought a plot of ground 200 x 300, covered it about half, so that we could easily handle 4,000 lights in our city. We find now we must just duplicate that.

The one important point is to determine how large to build the station that it may serve its purpose for not less than 25 years. One of the ideas that suggested itself to me was to take the total gas output of the city, and on the basis of 16-candle lamps reduce it to steam power and provide for from two to three times the total gas output. Buy your land now for the buildings you will erect in the future, and you will find it much cheaper. So far as we know to-day, we have got to rely on steam power. Locate your boiler with reference to the whole plot of land. Make arrangements with your engine in the same way. Then put in your first ones and follow that plan out. When you have determined by the rule of taking your gas output, divide your power into about ten units; ten engines.

As to what engine to recommend, I do not believe that I shall attempt to offer any suggestion. We decided to adopt, and have erected, a triple expansion engine built by Allis & Company, of Milwaukee. We have had it in operation now for about four months, and we have never had the slightest trouble with it. It has done admirable service, and although it has not yet been tested, it gives great promise.

When you set about constructing your station, it should be of a permanent character, and there should be made very large and liberal arrangements for the growth of your business. If that is neglected, there will be the universal inconvenience which has already been suffered from starting up in a hen-roost or under a shed outside. I believe the loss of money in this direction is greater than in any other in central station experience. The fact is, the day has gone by for that sort of thing.

The strong point I wish to bring out is the providing of ample space or ground. Buy it and own it. It is what you want for future growth and development. That is certainly a pertinent lesson that has been taught us by the universal experience of all men engaged in central station construction.

Mr. M. J. Francisco—I would like to ask the speaker if he recommends independent condensers?

Mr. Perry—We had designed for our station an independent condenser operated by an independent engine, and it had some unusual features. It is the first cut-off cylinder that was ever put on a condenser that I know of. We have been operating with that since about the middle of December, and it has been very satisfactory. We have a guaranty as to the steam or water consumed in developing a certain amount of power, so that it is to be brought down to the same level of economy as the main engine. The condenser which we are operating is a condenser designed to handle easily 2,000 h. p. Our first engine is in, and we have worked it up to 750 h. p., and have never had a minute's uneasiness. It has never been shut down an instant. It has operated so satisfactorily that we have now contracted with the builders, and they are at present constructing for us another engine of the same stroke, the same diameter of fly-wheel, and intended to drive on the same shafting up to 1,500 h. p.

Mr. Fred E. Sickles, the veteran inventor, then read an extremely interesting paper on "The Steam Engine."

After giving a valuable discussion of engine design and construction, Mr. Sickles said :—

"In regard to the steam engine of the future, if a metal is found that will enable steam of, say 1,000 degrees to be used, and the escaping heat from the first boiler to be used in evaporating water to feed a second engine at 500 degrees, and then to a third engine that will make the draft by drawing the heated products of combustion through water whose evaporation will supply a working cylinder that derives its power by receiving the steam below the atmospheric pressure and expands it to the lowest effective limit before discharging into a condenser—then we will have a combination using much less water per horse-power than any engine yet made; but it does not follow that such an engine will be the most economical, as that will depend upon the interest charged for the use of money and the price of fuel, as it would cost more per horse-power to build such an engine than one working under ordinary conditions. With money at 6 per cent. per annum and the cost of fuel to evaporate one ton of water at $1, a certain plan would be advisable. Again, with the money at 3 per cent. per annum and the cost of fuel to evaporate one ton of water at 50 cents, the same plan would be good, but as the cost of money and the cost of evaporating water change relatively, the best plan for economy in a steam engine would necessarily change to obtain the most economical result in the use of money. The cost of room for the plant and the cost of water for condensation, together with other contingencies, must be considered in any plan for a steam engine that is to be adapted to the surrounding circumstances under which it may be required to work."

THURSDAY, FEBRUARY 13—MORNING SESSION.

Mr. George H. Babcock's paper "On the Economical Generation of Steam for Light Stations," was read by George E. Palmer.

Mr. Babcock's paper, which was full of suggestion and caution for constructing engineers, contractors and lighting companies, was happily summed up at the end, by the writer, as follows :—

First. The use of the fuel which gives the best results for the least money. This varies with the locality.

Second. A furnace which will burn the said fuel to the best advantage, and at the same time permit of the rate of combustion to be quickly changed to meet the greatly varying demands without serious loss of economy between the highest and the lowest.

Third. A boiler which will utilize the heat to best advantage; which will give dry steam; which will permit of being forced much above its average rating for short times, without serious loss of economy; which is safe against destructive explosions, and which is not liable to frequent, difficult or costly repairs.

Fourth. Foreman and firemen with brains enough to employ all these things to the best advantage, and keep the apparatus at a point of maximum efficiency.

In selecting these elements of an economical plant it is urged that the co-efficient of common sense should be fully employed, and that facts gained from long experience are a far safer reliance than mere assertions not backed by years of practical results.

DISCUSSION ON THE PAPERS OF MESSRS. WOODBURY, SICKLES AND BABCOCK.

Mr. F. E. Sickles spoke in commendation of several points in Mr. Babcock's paper, particularly approving the provision of boilers that could be forced to extra duty for short periods without injury.

Mr. T. Carpenter Smith also approved the same point made by Mr. Babcock. If you can force your boilers during these two or three hours, by keeping the fires clean and being ready for the heavy load when it comes, you not only save the cost of a surplus boiler plant, but you save very largely in fuel consumption. He knew of a station where the fuel consumption was increased 50 per cent. by the necessity of having to fire up the second boiler for the two or three heavy hours' duty between four and eight o'clock. He knew there was strong prejudice against forcing boilers on the score of danger, but did not think any electric light station should be run by a man that could not be trusted to force a boiler without endangering it.

Mr. C. J. Field, of Brooklyn, N. Y.—I do not think we ought to pass over Mr. Woodbury's paper submitted yesterday, without looking at it a little more carefully. We all know what Mr. Woodbury has done in New England mill construction, which in the last few years has done more to bring up the standard of buildings of that class and make them safer against fire, than any other class of construction in the country. And when we see that these principles can be applied to small station construction, I think they are such as the electric light companies ought to know and give attention to.

Mr. M. D. Law—Mr. Woodbury has given us an explanation of a baby station. It is of hardly sufficient size for even a country town. In our experience it is far better to build a two-story station, having your dynamos on the upper floor, in order that there shall be no posts or wires projecting up from dynamos to interfere with the rapid moving of machines from one portion of the room to another, or the changing of armatures. As the continuity of your lights is the criterion of your success, you want to have your machines in such shape that an armature can be rapidly changed, and also that if the machine flashes that the dynamo man can get there quickly, and that that machine may not flash the second time. Flashes mean rebates, and they are very expensive.

Mr. S. E. Barton—I believe that more than three-fourths of the fires that have occurred in stations have been due to carelessness, to want of cleanliness. I believe further that a thing that is very sadly overlooked in the care of central stations is the condition of oil aside from the waste itself. A large amount of oil is allowed to accumulate on the station floors about engines and dynamos, so that when once a fire occurs from any cause whatever, the material of the most inflammable nature is there to spread the fire in a perfect flash from one end of the station to the other. The air and floor are filled with volatile inflammable substances from the oil. I believe it is easy to keep the floor of a generating station as clean as a kitchen floor. I believe the floors should be made of hard-wood and should be kept free from oil by washing at least once a week, or twice a week, if necessary. We have any quantity of stations in that condition to-day, where you could scarcely soil a cambric handkerchief on the floor except from the coal that is tracked in. If a fire starts it can not make any headway. When a station is constructed as Mr. Woodbury designs, it would burn slowly. The keeping of a station clean by washing the floors in some instances can not be well and safely done with the present practice of running wires from dynamos down through the floor, for no purpose that I can conceive of, except for the purpose of bringing them up from the floor again. I know of no reason why wires can not go direct from the dynamo overhead in plain sight.

Mr. C. J. Field then read a paper on "Development of Generating Stations for Incandescent Light and Power." (See page 101.)

DISCUSSION OF MR. FIELD'S PAPER.

Mr. A. P. Seymour, of Syracuse—It seems to me, there is one rule that can be applied to all localities. That is the rule of using common sense which can be applied everywhere and under all conditions, to great advantage. Another rule that can be applied everywhere, is to do your work well. If you can't afford to do it well, don't do it at all.

In our station we are using Corliss engines. We used to use high speed engines, but we took them out and put in the Corliss engine, and we have found that our saving is about 52 per cent. in fuel. Of course we are in favor of the Corliss engine. Our conditions of course are different from those of an incandescent station.

Mr. Armstrong—Assume that we were only earning enough to pay our expenses. I suppose by the expenditure of a little more of that which Mr. Field has termed "variable expenses," that I could double receipts, and that seems reasonable. I could double my revenue, by an increase of say 25 per cent. in my expenses. If that is not so, then it seems to me, that electric lighting is rather a peculiar business. I am looking for the dollars and cents; that is what I am in the electric lighting business for. I am not a scientist. This association represents a great business, and, therefore, this point is something that we ought to have particularly cleared up. I am more pleased with this paper than anything I have heard here at the convention.

Mr. Field—If you increase your plant you of course get an additional income. I have assumed that increasing your outlay, your capital is going to increase proportionately, and that you will not add a debt on which you must pay interest.

Mr. Alexander—Mr. Field said that within five months they had but one cross which they blew out. I suppose he meant that they burned it out. I want to ask whether the third wire was grounded, and secondly, whether he considered it safe to blow out a cross? I think if you do that you increase the danger of electric lighting considerably.

Mr. Field—The question of grounding the neutral wire on a three-wire system, has not, I think, been thoroughly settled. But it is a thing that has to be left to the individual judgment of each manager. It varies in different systems. You strike some old systems where they practically have not grounded their neutral wire owing to defects in their underground system. They have done that to avoid a cross between their two outside wires.

As to blowing off the ground: When you get a heavy cross on your underground system, what are you going to do? You must shut down or blow it off. I do not think you are taking any great chances. I have seen a good many blown off, and I never knew them to give trouble. They will make the lights shake for a few minutes, and then you will go on serving your customers just as you did before, and take your time to hunt up the cross.

Mr. T. Carpenter Smith, of Philadelphia, then read a paper on "A System of Station Accounts." The paper was devoted to the description of a system of doing work and keeping cost, that could be used in stations of any size, and at the same time enable fair comparisons to be made between them.

Mr. Smith recommended a systematic division of duties between the officers, staff and employés, together with a simple, but comprehensive classification of orders and accounts such as would lead, in the counting-room, to a clear and easily intelligible record of the various departments of the service and the cost of operation under concurrent heads, useful for studying the progress of the business of a station, and for comparing its results with those of other stations.

The methods of administration and accounting set forth were substantially similar to those employed largely in corporations, adapted to the peculiar requirements of the business of electric lighting. The main principles are that no work should be permitted, or at least paid for, except upon written order from a proper official—and then all expenditures whatever should be charged to the account of definite orders; either standing orders or special orders.

At the conclusion of Mr. Smith's paper, the secretary stated that a letter had been sent to the association by Mr. Fred H. Whipple General Manager of the St. Louis Exposition company. Its purport was that the St. Louis Exposition company had requested the American Institute of Electrical Engineers, the National Electric Light association, and the electrical fraternity at large, each to appoint one of a committee of three to pass upon the awards of merit and the medals to be given at the St. Louis Exposition. Mr. Garratt said the American Institute of Electrical Engineers had named Professor Carl Hering as its representative on the committee. Mr. Edwin R. Weeks was then selected as the representative of the National Electric Light Association.

THURSDAY AFTERNOON'S PROCEEDINGS.

Mr. A. J. De Camp, of Philadelphia, addressed the association on the "Cost of Products to Central Stations."

Mr. De Camp explained the methods employed by his company in deducing the revenue per lamps and cost per lamp.

Having arrived at the cost of production, no man, he thought, could prosecute his business and take care of it without being familiar with the various items of which that cost is made up. He saw fit to divide that under, first, pay roll; second, general expenses; third, taxes; fourth, interest; fifth, extraordinary; sixth, coal; seventh, carbon; eighth, engines (repairs and maintenance); ninth, dynamo; tenth, lamps; eleventh, lines. He divided the pay rolls into three classes. First, the electrical department; second, the motive power department; third, office pay roll. The general expense was grouped into stationery, carriage (express—freight—horses), tools, and miscellaneous items.

He thought it a mistake to assume that income from increase in business so far outstrips increase in the cost of production. In a respectably sized station, suppose that an increase of from 600 lights to 800 is made, and results in an increase in cost of 10 per cent.; an increase of 25 per cent., that is, from 800 to 1,000, results in an increase of 8 per cent. in cost; an increase again of 20 per cent. results in an increased cost of 7 per cent.

DISCUSSION ON STATION ACCOUNTS.

Mr. Francisco—I consider this matter of central station accounts as one of the most important subjects that a central station man has to deal with. During the past year I traveled from Boston to Washington Territory, and as far south as this city, taking in nearly all the stations, numbering several hundred. In the course of interviews with the station men I found that a large number, in fact the greater portion of the ordinary stations, small stations, kept no classified accounts whatever. They run plants, their engines and lights, and at the end of the year struck a balance. In a great many cases they found the balance on the wrong side, but they could not tell where it went to. If the central station men will adopt Mr. Smith's plan of accounts throughout the United States, it will be of great assistance. There are some of us who may not want to give away our secrets, but if I find one man whose lights are costing him a certain amount of money, while mine are costing a good deal more, he will afford me an explanation, and give me the benefit of his experience. If you do not keep track of your expenses in those things, they will eat you up.

Mr. Field—The stations which I have taken my basis from have been incandescent stations, while the stations Mr. De Camp has referred to are arc light stations. That will explain much of the apparent difference in the results. Mr. De Camp doesn't say where on his list he gets his fixed expenses and his variable expenses.

There is one company that receives reports from 100 or 200 of its central stations, not of details, but of general expenses, operating expenses and earnings, and publishes them each month for the benefit of their other stations. From this it will be seen that one station is using so much coal, and producing a given result. Of course there are local conditions. One place gets coal at 10 cents per ton, and another pays $5 per ton, and these are things that must be taken into consideration. But when you take into consideration all these things, you get a result that will show where your mistakes are, show where your men are not doing right, and point out the remedy.

In regard to the proportion of variable and fixed expenses, I will say, that since this morning I have been looking up a few facts and data, and I find one large station is down as low in variable expenses as 21 per cent. of the total expenses. In other words, that station has doubled its business, and has only increased its expenses 21 per cent.

Mr. T. Carpenter Smith—I have been asked several times how to handle the depreciation account. I do not know of any better way of doing that than by having no extraordinary account, but one repair account; the repairs cost so much from year to year. The fact that we have had a smash-up and that repairs cost us a little more for one particular month ought not to have any effect with the directors when it was explained. But if at the end of the year it would appear they were too much, they should be looked into. We should want to keep our account near the point which was settled upon as about the true basis. That is to say, every time there is put in a new engine, or a new dynamo, or a new boiler as an addition, it should be charged to construction account. But when you find that the engine is worn out, and you want to change it, you charge the new engine to repairs and sell your old one for what it will bring. The only increase in your capital account are your legitimate construction expenses. It is the same in a pole line. If a new pole goes in where there was a pole before, that is charged to repairs.

President Weeks—If you will pardon me, Mr. Smith, what do you do if there is a change in the market value of material?

Mr. Smith—That you will have to charge to repairs the same way. You will get the benefit of the cost when you put in a new machine.

President Weeks—We can all remember when a sewing machine cost from $100 to $150, while we can now buy them at from $10 to $30. Will not the same be true, to a considerable extent, with regard to electrical apparatus? What will you do with that shrinkage?

Mr. Smith—If you bought a dynamo for $1,000, the first year it is worth $1,000. Every year your dynamo decreases in value; it gets worn out. When you get your new dynamo in, you get it for less money. Your capital account remains the same. You have otherwise to make a gradual drop in the value of your plant in making your annual statement. I want to get rid of the depreciation account by making it all repairs.

Mr. De Camp—A rule which, I think, is a good one in this depreciation account is this. The depreciation account is an unknown quantity; it is a conservative way of guessing at things or keeping account. A rule like this will always enable you to be on the safe side. Merely incidental repairs are not things, that affect it one way or the other. But when it comes to the general repairs, and you work on this principle, if after these repairs are made, is your engine or your dynamo or your boiler as good as new? Then your construction account is not affected. Overlook all charges or all depreciations, if not connected with any general expenditure of money.

Mr. Smith — I would explain, in speaking of the capital account, that it is always a liability. In estimating your assets, it would be a simple way to keep these assets from year to year to put them in at the value for which you think they could be replaced.

Mr. F. A. Wyman, of Boston—My experience has been that this so-called construction account should be called a destruction account. This running of expenses into the construction account destroys or ruins more people than any other item in the business. It does not seem to me right to build a new station, run it ten years, let it pay 10 per cent. per annum, and at the end of ten years have to build it completely over again; so that your plant is only worth 50 cents on the dollar. It seems to me it is better to start out and pay a five per cent. dividend and charge the other five per cent. to depreciation. Of course, it takes courage to charge this up. A party making lights very cheaply, and having exclusive control of a city in which he is getting a high price, tries to make his operating expenses as large as they possibly can be made; but in a small town where there is only a small dynamo capacity, they try to make their construction account as large as it can be. You have to steer between the two. I wanted to give you a practical illustration. About 20 years ago there was a gas plant started in a good-sized town in the east with $100,000 capital. The other day in looking it up, we found they had a paid-in capital of $85,000. They had $35,000 worth of property left. The other $65,000 had been paid away in dividends. They hadn't kept any depreciation account; it all went into the construction account.

Mr. J. J. Burleigh, of Camden, N. J.—I think there should be no such an account as a depreciation account. In arriving at that calculation I was interested in watching the plan of the Pennsylvania Railroad Co., who have given a great deal of attention to accounts and the best plan of arriving at values, and they do not have any depreciation account. They aim to keep their road and its equipment up to the standard all the time, and charge it to expense. Anything new that aids their railroad is charged to capital, and that which replaces what is worn out is charged to expenses. Take the case of a locomotive which is valued as scrap at perhaps $1,000. That is replaced with a new engine costing $8,000; which is charged to expenses. They know exactly what they have got; and so can we know. They want to know whether they have a railroad worth what they have it capitalized for. We want to know the same thing. They have to take an account of stock, just as we do. They know just what the value of their railroad is. We are so particular in our company in Camden that we have everything in that direction go to expense. If we find by an account of stock that the values of what we have on hand are not what we are capitalized for, the board takes action and charges it to expense.

Mr. J. E. Lockwood—I believe the nearer we can know each month what we do, and not have to wait until the first of January or whatever date we take our inventory, the better we will be informed and the better we can carry out the improvements suggested by the results. I had a case in point in a company with which I was connected. We found just what the major part of our accounts was per month, such as coal and labor and accounts of that character, and we charged this into the total running expenses for that month. Then we found that the interest and taxes and accounts of that description, repairs included, varied very greatly. The interest and taxes it is true, we had to pay only once a year, but the repairs we studied over and arrived at this solution: We created what you might call a balancing sheet, and we estimated at the beginning of the year how much we would likely have to charge up during the year for taxes, insurance and accounts of that description, and then we started in and charged up each month in our monthly sheet what we thought was the proportion that that month would have to the total year. If we did not pay our taxes until the ninth month in the year, there was accumulated upon this balancing sheet during those nine months certain amounts, and we credited the same amounts in the monthly sheets as in the balancing sheet, and then taking the proportionate amount of that nine months we charged up the proper proportion in the remaining month. We adopted the same system for repairs. Instead of charging up each month just what the repairs were, we estimated as nearly as possible what they would amount to in each year, and then charged up one-twelfth of the amount we had estimated for the year, and as the end of the year drew near, we could see on our balancing sheet what was going to throw us out of our estimate. We divided it among the remaining months, and charged it up proportionately to each month in the year. I believe that in this way we will better know how to make improvements from our investigations.

Mr. G. M. Phelps, of New York, here read, for the information of the association, the following telegram which he had just received:—

"New York, Feb. 13, 1890.

"George M. Phelps,
"Coates House, Kansas City.

"Just returned from Richmond where bill for restriction of voltage in Virginia has been reported adversely by the unanimous vote of the senate committee after two days' argument. It was supported by Edison in person, and the electrical executioner; it was opposed by Westinghouse representatives, aided most efficiently by local companies at Norfolk, Alexandria, Petersburg, Lynchburg, Fredericksburg, Richmond, Liberty and others. R. W. POPE."

Mr. M. D. Law then read a paper entitled "Nine Years With the Arc Lamp." (See page 99.) This was followed by a paper on "Carbon Tests," by Mr. E. F. Peck, read by Col. C. N. Ransom, in the absence of the author.

DISCUSSION ON THE PAPERS OF MR. LAW AND MR. PECK.

Mr. Francisco—If it is not a secret of the business, I would like to ask Mr. Law with what instrument he tests grounds at the stations.

Mr. Law—I do not know that there is anything about our station that we call private. I have been testing grounds for the past year or eighteen months by the use of a set of incandescent lamps in series. I use 60 47-volt lamps for a 60-light arc circuit; these lamps are put up out of the way and a wire run from each to the switch plate. There is a lever arranged to turn in a circle making a short circuit of one, two, three, four, five, etc., to cut-out one or all of these lamps. Now, if a ground occurs from the station it is simply a measure of potentials. Every two hours we test each one of our circuits, first testing across the circuit. The number of incandescent lamps then burning up to 47 volts, indicates the number of lamps that are actually burning on the circuit, less the resistance of line; then we test by placing one side of the incandescent circuit to ground and the other side to line; then by turning off my incandescent lights until I bring the voltage up to 47, I find a certain number of lamps burning. We will say 10 lamps on the positive side; now I turn my attention to the negative side and go through the same operation. If I find that I have 50 lamps on the negative side, I know that the ground is 10 arc lamps away from the station on the positive side, and if your circuit books and diagram books are correctly kept, you can tell in two or three minutes exactly the location of that lamp. In 99 times out of 100 we go to the right lamp.

Mr. DeCamp—In Mr. Peck's paper he speaks of an arc lamp being burned at the Centennial in 1876. I will ask if any gentleman present saw that light? I was at the Centennial probably a hundred times and never saw it.

Mr. Garratt—I did not see the lamp at the Centennial, but as a matter of early history in regard to the arc light industry in this country, I did see an arc lamp run in Boston, in 1865; that, however, was not to be called commercial in the sense in which you use it to-day. It was an arc lamp with clockwork feed.

Mr. Lockwood—While I did not see any lamp at the Centennial, I will state that Frauk B. Rae, of Detroit, will give Mr. De Camp the information he wants. My reason for thinking so, is that Mr. Rae gave me not long ago an account of an interesting experiment he made at the Centennial. He found that by making a flat helix of fine wire and connecting it with the receiver of a telephone, he could approach a dynamo and before he got within, say five or six feet, and sometimes 15 or 20, by holding it out ahead of him, and moving it through the air, he would get induction, and then by comparing that with the tones of a flute that he had attuned to respond to a certain number of vibrations, he could tell the number of revolutions the dynamo was making by multiplying by the commutator sections.

Mr. F. S. Terry, of Chicago—I will say that I saw that lamp in Philadelphia.

Mr. H. W. Pope's paper on "How Our Paths May be Made Paths of Peace." (See page ——), having been printed and distributed, was taken as read.

The paper of Professor Elihu Thomson on "Safety and Safety Devices in Electric Installations" (see page 95), also printed and distributed, was taken as read.

DISCUSSION ON SAFETY DEVICES.

Mr. Lockwood—I am sure that every member of this convention must feel in the present condition of electric lighting the need of safety devices. I do not want to be understood that I am now using in my station every device that I advocate; but they will all go in with the greatest possible despatch that I can get them in, and do the work thoroughly; then I am going to keep our station in the matter of safety devices at the head of the list as far as lies in my power.

Professor Thomson speaks of the fact that the dealing with the wire question by the authorities in New York city has been very severe, but yet thinks it will lead to final benefit to the electrical interests. I think that depends upon no one thing more than on how we keep our circuits supplied with safety devices from this time forth. I think if we do not pay great attention to adopting means for denoting a ground when it occurs on a circuit and then locating it and finding how it can be removed in the shortest possible time, and seeing that in all ways they are kept clear and free, we will not have the success that we ought to have.

Mr. Law—In lightning arresters I think we have a very important species of safety device. Not only do they protect the dynamos, but they protect the insurance companies against loss by fire. Before the adoption of lightning arresters in Philadelphia, we had three fires in buildings which were caused by lightning coming in on our lines; but since the introduction of lightning arresters we have lost no dynamos and have had no fires. Another important feature of lightning arresters is their protection to underground cables in taking up the so-called static discharge of the dynamo on the interruption of the circuit. The matter of cut-out boxes is another very important feature. They should be placed on every part of the circuit where it goes inside of a building or is attached to a building or a loop going over any street. It gives you perfect control of that circuit in case of fire. That was clearly demonstrated to me about two months ago at a fire in Philadelphia. I was at the fire very soon after the alarm, and found we had a loop going up in the rear of the building. I discovered there was no box upon that pole, for which my foreman received very severe censure.

Captain Brophy—I wish some one who had better control of the king's English than I, would do justice to the barbarous treatment the electrical fraternity has received at the hands of the so-called underground commission of New York. I agree with Professor Thomson in all he says in regard to that subject. A few men selected without any regard to their qualifications for the positions they hold, sit in judgment and throw a large city in total darkness without making any provision for any other form of light, and as it were, turn the whole city over to the hands of thugs and criminals. I believe myself that the insulation of overhead wires is only a question of dollars and cents saved to the parties who are operating the central station. I do not believe it solves the problem of preventing accidents to life and accidents by fire. An unused wire that no one cares about can drop down and saw its way through in half an hour, and some one will come along and complete the circuit from the wire to the ground and be the victim, and the press sends the news all over the land, giving no explanation of how or why it was done. So far as safety to the public is concerned, if you will run your wires well up in the air, if you can get the right of way to do so, it matters little whether they are bare or insulated. Until the municipalities or some other power will protect you from *tramp* wires, the poorly constructed wire, and the many other roads through which death and destruction may be carried, you cannot be held responsible for these accidents, and until you have the right and the clear right to run your wires without being menaced by such things as these, you cannot prevent accidents of this kind.

The secretary read the report of the committee on data as follows:—

REPORT OF THE COMMITTEE ON DATA.

The membership of the committee as now constituted is as follows: A. J. De Camp, C. R. Huntley, E. F. Peck, Edwin R. Weeks, Allen R. Foote. This committee has printed in pamphlet form and distributed to central station companies, the paper read at the tenth semi-annual convention of the association on "The Value of Economic Data to the Electrical Industry." Accompanying this pamphlet, a circular of inquiries was sent, inviting suggestions as to the items of data which those addressed considered desirable to be collected, also the forms of accounts, reports, which may be used to establish a uniform system of accounts with a view of rendering the data obtained from them reliable and valuable.

The responses received, by correspondence and personal interviews, leave no doubts in the minds of the committee as to the general appreciation of the value of the work to be undertaken and of the cordial co-operation of central station companies in carrying it to a successful consummation.

In view of the fact that the United States census office is now engaged in preparing schedules for obtaining certain data relating to the electrical industry, this committee thinks it best to suspend the work of formulating reports for the purpose of obtaining data until after the work of the census office shall have been officially published. The committee can then devise such reports as may be supplementary to, or a continuation of, the work done by the census office, thus increasing very greatly the value of the work it may do.

With the above object in view the committee has given special attention to the work of assisting the formulation of a special schedule for central station companies for the use of the census office. The outlines of this schedule have been submitted for suggestions to upward of thirty of the largest companies in the country. A representative of each company has gone over the entire subject in detail individually, and made such suggestions as seemed to him to be pertinent. The entire schedule is now in process of revision in the light of these suggestions. When this work is accomplished it will be again reviewed by this committee. In case the schedule as then submitted is satisfactory, this committee requests the authority of the association to approve of the schedule in the name of the association.

The first decade of the history of the electrical industry was necessarily the decade of theory and experiment. A decade in which large sums of money have been invested on the basis of representations made by manufacturers as to what their apparatus or construction was expected to do. During this period, the time of the conventions of this association has been largely consumed by long, and sometimes exciting discussions over this or that feature of the business in which all were engaged. No satisfactory solution has been reached by such discussions, because arguments were based on what was expected to be, instead of upon what was.

In entering upon the first year of the second decade of electrical history, it will be well for the association to draw a sharp line of demarkation and cease to discuss subjects from the standpoint of theory. It should substitute therefor the standpoint of facts. Not that the days of theory and experiment are over, that will never be. But the days are over when to have an electric service at all, it must be accepted on faith in promised results. The time has come when we can afford to wait for the adoption of a new idea, or new application of an old idea, until it has been put into practical use for sufficient time to enable their claims for general adoption to be based on accomplished results. Whose cause cannot be served by truth, should not be served.

Mr. Garratt called attention to the seventh clause of the report, and thought the phrase, "entering upon the first year of the second decade of electrical history," should be amended so as to read, "Electric light history." Electrical history ran back several centuries.

The report was adopted, and the committee continued.

INVESTIGATION OF ELECTRICAL INDUSTRY FOR THE CENSUS.

Mr. De Camp presented the following preamble and resolution:—

Whereas, The Superintendent of the United States Census has appointed a special agent for the investigation of manufactures of electrical apparatus and supplies and their uses; and,

Whereas, This is the first official investigation that has ever been made of this subject in this or any other country; and

Whereas, It is the opinion of this association that such an investigation will be of the very highest value as a means of furnishing the public with information that it can accept as being reliable, impartial and authoritative, and for that reason will be of great value to those interested in the electrical industry; and,

Whereas, This association, in behalf of the electrical industry of the United States, desires this investigation to be thorough and complete in every detail, and is aware that such an investigation could not have been fully authorized and provided for, on account of the newness of the industry, when the law providing for the census of 1890 was enacted—

Be it Resolved, by the National Electric Light Association, in convention assembled,

First.—That it respectfully petitions the Senate and House of Representatives of the United States Congress to authorize and direct the superintendent of census to collect the following data in relation to the electrical industry, in addition to the general statistics of manufactures already provided for by law:

(*a*) Details pertaining to underground and aerial construction, underground and aerial currents, the character and voltage of all currents, and their uses. Lamps in use, arc and incandescent, and how wired for residence, commercial and municipal service; motors in use for stationary service and motor cars; income and expenses, etc.

(*b*) An inquiry through sources independent of those interested in the industry, as to the casualties resulting from the use of electric currents, both as to fire and personal injuries; this investigation to be made in all cities of ten thousand population and over; the information to be obtained from underwriters, the records of fire departments, coroners' statistics, health boards or commissioners, or from whatever source of information that may exist in any city; the investigation to make a comparative statement between the casualties resulting from the use of electric currents, and the use of other agents employed for similar purposes.

Second.—That we hereby petition that an appropriation of not exceeding $50,000 be made for the purpose of this investigation.

Third.—That the National Electric Light Association hereby tenders its thanks to the Hon. Robert P. Porter, superintendent of census, for the recognition he has given to the importance of and wonderful progress made by the electrical industry, in the appointment of a special agent for its investigation, and we hereby pledge our cordial co-operation with the census office in its efforts to make the investigation thorough, reliable and complete in every detail.

Fourth.—That a copy of this preamble and resolutions be properly engrossed, officially signed by the president and secretary of the association, and transmitted to the chairman of the committees on census of the Senate and of the House of Representatives, and to Hon. Robert P. Porter, superintendent of census.

The resolution was adopted.

FREIGHT ON CARBONS.

Mr. Lawrence, of Cleveland, then offered a resolution, which was handed to the secretary.

Mr. F. A. Wyman, rose to the point of order that all resolutions should go to the executive committee and be approved by them before being presented to the association.

The president announced that the resolution was referred to the executive committee.

Mr. De Camp—On what rule of the constitution is that based? A resolution is presented, not read, and you announce that it is referred to the executive committee.

The President—It is based on the provision of the constitution that the executive committee shall arrange and provide for the programme and the order of exercises.

Dr. Mason—Have you given us the only authority for your decision?

President Weeks—That is the authority. There is in addition to that the fact that it is submitted by an associate member, and should come through an active member.

Dr. Mason—I understand that associate members have all the rights except those of voting, as recited in the constitution.

President Weeks—The decision of the chair is based upon the provision in the constitution. It is immaterial, however, if it meets with the concurrence of the convention.

Dr. Mason—I would be glad to have that matter decided by the association, through an appeal from the decision of the chair. I imply no disrespect in the appeal.

President Weeks—Certainly not. My ruling was on the way the matter presented itself to me.

Dr. Mason—I appeal from the decision of the chair. I think this question is a very important one and should be settled now. I do not think it was the intention of the association ever to repose in the executive committee such an exclusive power as this: that no business can get to this association except through the executive committee. If that is what is meant, let us know it.

President Weeks—I do not understand that to be so; but matters pertaining to the arrangement of programme and exercises—all such matters must come through the executive committee—as is distinctly stated by our constitution.

Dr. Mason—Of course we are all in the dark, I presume as to the character of this resolution, but I would like to have it decided whether a member of the association can present a resolution to the association direct, or whether it must go through the hands of the executive committee.

President Weeks—I think it can be presented directly to the association, if there is no interference with the order of business upon the table. There being no interference in this case, I think I will have to reconsider the position taken upon that. (Applause.)

Mr. Wyman—Mr. President. I rise to a question of privilege, and ask if it is not clearly stated in the constitution and by-laws that all papers and resolutions that are presented before the association shall pass through the hands of the executive committee?

President Weeks—It does not state all papers. I will ask the secretary to read that section of the constitution.

The Secretary—The constitution says that "the executive committee shall be the governing body of the association; that it shall meet upon the call of its chairman from time to time, and shall report upon application for membership, shall gather proper information upon topics of interest and see they are arranged for discussson by the several members of the association. Five members of the committee shall constitute a quorum."

Mr. De Camp—I may state that I have been a member of the executive committee, either direct or ex-officio, ever since I have been connected with the association. The executive committee have been in the habit of revising the papers which have been presented, for the purpose of relieving the association of the cumbersome amount of papers to be read for discussion before the convention. It has always been the case that there was more good material presented than it was possible for us to get through with; and, therefore, all such papers were referred to the executive committee to decide which were of the most general interest to the association.

Mr. Wyman—I would like to ask the gentleman who was last up if it was not the feeling at Niagara Falls that all things should go before the executive committee, in order that advertising schemes should not be thrown on the association.

Mr. De Camp—I presume if the resolution should take the form of an advertising scheme, the association is perfectly competent to sit down on it peremptorily.

Mr. Alexander—Mr. President, if an associate member appeals from the decision of the chair, how do you decide that point? Can an associate member appeal from the decision of the chair?

President Weeks—No, sir; I think not.

Dr. Mason—Does not the constitution recite that associate members shall have all privileges except those of voting.

President Weeks—An appeal from the decision of the chair, is a privilege so nearly akin to that of voting, that in my opinion it comes under that exception.

The matter was in fact presented by an active member. We will admit the resolution.

Mr. Wyman—I move the resolution be laid on the table.

Dr. Mason—That cannot be done until it is read.

Under the direction of the president, secretary Garratt read the resolution, which was as follows:

Whereas, The present classification of electric light carbons is much higher than other commodities of corresponding weight, bulk and liability to damage, packages less than car lots being rated as first class and carload lots as third-class; and this classification was made years ago when few carbons were manufactured, when they were high-priced and supposed to be very liable to damage, but are now among the cheapest shipped, are compactly and securely packed, easily handled, and not liable to damage in the ordinary risks of transportation, which is demonstrated by the fact that no claim for breakage of, or damage to, carbons has ever been preferred to the railroad.

Therefore. Be it resolved that the National Electric Light Association in convention assembled, considers the present classification unjustly burdensome, and believes the interests of all electric light companies will be promoted by reducing the classification, and that greater volume of traffic and corresponding gain to the railroad companies will accrue.

And be it further resolved. That this association indorses the efforts of the committee of carbon manufacturers appointed to make application to the general freight classification committees of the United States in furtherance of this resolution.

The resolution was adopted.

The following committee on nomination and place of meeting was appointed, Mr. Huntley, Mr. Francisco, Mr. Beck, Mr. De Camp and Mr. Beebe.

Mr. De Camp—I move you that when this convention adjourns that it adjourn to meet in the month of August, 1890, at such a day as the executive committee shall decide, at Cape May, New Jersey.

The motion was adopted.

FRIDAY, FEBRUARY 14—MORNING SESSION.

Mr. C. R. Huntley presented the report of the committee on nominations, as follows:—

President, M. J. Perry, of Providence, R. I,

First Vice-President, E. W. Maher, of Albany, N. Y.

Second Vice-President, C. L. Edgar, of Boston, Mass.

Executive Committee, C. R. Huntley, chairman; E. R. Weeks, Kansas City, Mo.; James English, New Haven, Conn.; S. A.

Armstrong, Camden, N. J.; M. D. Law, Philadelphia, Pa.; M. J. Francisco, Rutland, Vt.; A. F. Mason, Boston, Mass.; John A. Seeley, New York; H. K. Thurber, New York.

Dr. A. F. Mason—I desire, sir, in a word of explanation to make a nomination. I think that every member of this association recognizes, with something akin to gratitude the very felicitous, the very remarkable, services of the present president of the association. I believe that I do not speak for myself alone, but for every member, when I say that we have had an exceptionally profitable as well as enjoyable meeting here in Kansas City; and that very largely this is due to the efforts of our president, E. R. Weeks. I, therefore, desire to put in nomination, for the presidency of this association for the ensuing year, E. R. Weeks, of Kansas City.

Mr. De Camp, of Philadelphia—I arise to second the nomination. We certainly owe a proper appreciation to those who have already served us. I think I am justified in saying, of all the meetings that this association has held, there has been evidence of a healthy growth. But like the growth of our country, we have in that total growth made a stride. The step from our last meeting to the present, comes under that class. It is a stride! This is the most largely attended meeting that we have had. There has been the greatest interest taken in it, and our work has been of the most practical kind, and I think that it has been due very largely, if not entirely, to the efforts made by the president. He has been, during the last six months at work constantly, otherwise the results that we see could not have been accomplished. I would be glad to have him fully appreciate the feelings of this association.

President Weeks—Gentlemen, your action in this matter is gratifying to me, in that it evinces your approval of the administration just drawing to a close. Next to the consciousness of having done one's best comes the approval of one's friends and associates; but, gentlemen, my views of the presidency of this association have not changed. It is my opinion that the president of the National Electric Light Association should be a citizen of one of the larger eastern cities, one of the great electric centres, where he can carefully watch all movements affecting the interests of the industries that we represent. Kansas City is not such a centre, although Kansas City will sometime undoubtedly be just such a place and the place where, for this very reason, the president of some future convention of this association, might well be located; it is not so now. I have, during my administration frequently felt the disadvantage of distance; and if the interests represented in this association have not suffered, it has been due largely to the zeal and support of the eastern members; it has been due largely to the vigilance of our secretary and the earnest watchfulness, to the zealous application and industry of our executive committee. The success of this convention, gentlemen, which has been so kindly attributed to me, is due very much more to the combined efforts of those gentlemen who have supported the administration, and have looked out for the interests of the association so carefully.

For these reasons, gentlemen, I feel, much as I appreciate the honor that you offer me, that the best interests of the association require the election of the officers nominated by your committee. In the expression that has been made and in the increasing prosperity of the association, in the strengthening of it throughout the west, which was the reason for my acceptance of this office, I find my reward. I thank you, gentlemen, for your offer, but for the reasons stated, I must respectfully decline the nomination.

Mr. E. A. Armstrong stated that it would be unwise, both in justice to the duties of the position, and unwise from a personal standpoint, for him to accept a place on the executive committee. He suggested the name of Mr. Burleigh as a substitute.

A motion to substitute J. J. Burleigh in place of Mr. Armstrong on the executive committee was then put and unanimously carried.

On the motion of Mr. Phelps, the secretary was instructed to cast the ballot of the association for the officers and members named in the report as amended.

Mr. Frank J. Sprague, of New York, then read a paper on "Application of Electricity to Street Railways." (See page 105).

After a few commendatory words from Mr. Armstrong Mr. Sprague spoke in amplification of some points in his paper, among other good things, he said:—

There will be gradually in many of our cities an amalgamation of the electric light and railway interests. It seems to me that is the natural outcome, and I know that oftentimes the same stockholders are interested in both the electric light and railway companies. I am going to have very soon, in a little town in South Carolina, what I think is the most complete electrical station in the United States. Some associates and myself, being convinced that not only the electric light but the electric railway business was a good thing, from the experience we have had with it in the past two years, got hold of an electric lighting company that was earning a very reasonable dividend on its cost. The company had an electric railway franchise which was exclusive for thirty years, and which had been granted both by municipal and legislative action. It also had the general railroad privileges of condemning public and private property. The rights being exclusive not only in the two towns, but for the vicinity, for thirty years, and there being no railroad there, and there being established an electric light interest there, and there being no gas company, we thought the opportunity was an excellent one to carry out that idea which is always in the minds of electrical people, namely, the consolidating of electrical interests. We not only consolidate the electric part of it, but we consolidate the elements of management and personnel. We have different systems, the arc light system, the incandescent system, the power circuit and the railway circuit, all in the same building and under the same roof of the car sheds, and with all respect to the telephone interest, I think pretty soon we will have the telephone circuit. We are going to run telephone wires on the same poles with the others. We are going to demonstrate that it is quite possible to run a telephone circuit, an electric railway pole line not only in conjunction with it, but in conjunction with electric lights and incandescent lamps. We hope this enterprise will be profitable and that there may be a great many other places in which the same thing can be done.

Professor Eaton, of Liberty College—I would like to ask Mr. Sprague if he has any objection to stating what his principal reasons are for his conclusion that the storage battery system will not successfully compete with the overhead or direct wire system?

Mr. Sprague—It is this, the simple reason is that you cannot three times convert energy at the same economy that you can once. That is the first reason. Secondly, because you cannot carry a dead load of two tons around, unnecessarily, without energy—you cannot carry it around any way, necessarily or otherwise, without energy. You must carry your storage battery and you cannot get rid of that useless load. It weighs nearly two tons. It weighs as much as thirty-five or forty passengers. It weighs more than your motor equipment; it weighs more than your car body considered by itself; it weighs more than your iron trucks considered by themselves. We have to carry our motors around, we have to carry the trucks, the passengers, and the car bodies; but to carry our storage battery is another thing. There are no storage batteries in existence furthermore whose storage capacity will permit of more than 26 or 30 horse-power being taken out of it. If you limit the weight or size of your battery, you reduce its capacity. On grades of eight per cent., and that is about the maximum which the adhesion of the rail will permit, you find a great difficulty; you will use about 30 horse-power of mechanical energy, and the motor must develop that. There is no storage battery that you can put on a 16 foot grade to-day, out of which you can take that power for thirty minutes at a time; the capacity is not there. But when you get the overhead line or the underground conductor, provided it is connected with a big engine and a lot of dynamos at the other end, you can demand from that station all your motor can carry. There is no storage battery which a company dare recommend for operation upon a 6 per cent. grade, or that you could run 160, 170 or 180 miles a day. The maximum work of a storage battery per car, per day, is about 80 or possibly 90 miles, and there are very few cars doing that. There are no storage battery cars in the United States that I am aware of, that are working 18, 19 or 20 hours a day, as is the case with the direct system of supply.

I hope, as cordially as any other man can, that the storage battery is going to be a success; but there is no question that its limitations are pretty clearly fixed and that it can never compete with direct sources of supply in capacity. There is no limit to the capacity of the motor or the amount of current you can use from a direct source of supply. There is certainly a well defined narrow limit in the case of the storage battery. I say that with all friendliness to the storage battery, because I am interested financially in one—or rather I should say one is financially interested in me.

Mr. C. C. Haskins, of Chicago, then addressed the convention on the subject of "Prodigality in Economy," enforcing the still much needed lesson of liberal but wise expenditure as the only true way of establishing permanent economical conditions in electric plants, and illustrating his remarks by many telling examples of cheap work on the one hand and economical work on the other. The whole was well seasoned with racy anecdote and humorous suggestions, such as anybody looks for whenever Mr. Haskins takes the floor.

Mr. Charles A. Harber, of Kansas City, read a paper on "Line Insulation from the Standpoint of Practical Experience."

Mr. Harber said the question of the day for electrical industries was insulation, and that any information bearing thereon, derived from experience, might be valuable. He presented a brief record of measurements to determine the relative existence of several forms of insulation.

Among Mr. Harber's circuits, operating Thomson-Houston arc lamp (about 10 amperes at 50 volts) he had four varieties of insulation, viz:—P. & B., Simplex, Grimshaw and Okonite.

The external conditions of these circuits were nearly the same. The Okonite circuit in use 18 months, was 2½ miles long and operated 50 lamps; the P. & B. circuit in use 15 months, 2⅓ miles long, operated 40 lamps; the Grimshaw circuit in use 18 months, 2 1-15 miles long, 24 lamps; The Simplex circuit in use 13 months, was 3 7-10 miles long and operated 40 lamps.

During the 12 months ended January 1, 1890, measurements of insulation of these circuits had averaged: P. & B. 485,702 ohms;

Grimshaw 891,892 ohms ; Simplex 895,122 ohms ; Okonite 900,212 ohms.

Mr. J. E. Lockwood, of Detroit, then read a paper entitled : "How to Make Arc Light Circuits Safe." (See page 111.)

DISCUSSION.

Mr. Law—The explanation that I gave of testing for grounds is one of the first that has ever been presented to the association. It is a very good method, but still probably not as good as the one that you have just listened to. My reason for using a low voltage lamp was simply because it was easier to locate the ground, and it was easier for the men that were in charge of the station at that time to grasp the idea.

Captain Brophy—I believe any system of testing grounds on an arc light circuit, by a low resistance in the circuit of the ground is dangerous. The plumber and the gas-fitter, those worthy individuals who are a terror to all electric light men, get in their work, and an imperfect ground is established possibly between a gas pipe and an arc light circuit. It is desirable in testing to reduce the amount of current traveling over that part to the lowest possible amount. In addition to having a proper method of testing and clearing the line of the ground another very good thing to do is to clear your lines of everything in the shape of obstructions. There may be a wire run by a boy who has set up a bell somewhere, and whose fond parents believe he knows everything about electricity. Do not enter into any arrangement by which any grounded circuit can be run on your own poles and fixtures.

Mr. E. Gregory, of Chicago—We are running 300 arc lights. We have our chief linemen go over the circuits and see every foot at least once or twice a month. We use the galvanometer to take our measurements by. In that way out of seven circuits, for a period of over seven months, we have had no occasion to shut down for any line trouble. We haven't any newly devised schemes for locating grounds. Our circuits are all underground, running through alleyways. We have no air circuits at all, except where we come out of the alleyways. We come out and run into a building, and if it is only one or two numbers on the street we go right back into the alleyways. We think we have saved a good deal of money in that system.

Captain Brophy—I would like to speak upon one topic touched upon yesterday, and that is the desirability of some method of breaking the line without cutting it with an ax ; some method of disconnecting the lines in front of a building which is on fire, for the benefit of the fire department. There is no man who has studied up the sensational reports printed in regard to electric light matters so thoroughly as the average fireman. There is no man who dreads an electric wire more than he. After a wire is cut and let into the street though it be as dead as a door nail, he does not know it. If we had some method of disconnecting the lines from the dynamo by a system of switches, so firemen shall know the wires are perfectly harmless, it would be of great value to everybody interested.

Mr. Law—I can say that is practiced at the present time with us, and that every central station should send a competent man to every fire with the fire department. That has been done in Philadelphia now for nearly nine years. In some cases it has become necessary to shut down a complete circuit, where there was any danger of walls falling and breaking down the wires. I have provided in our fire wagon a cut-out which will hook over the wire, with steel pointed screws with a large wooden knob at the top, that a man can handle with perfect safety on any wire. Using that you do not have to cut away the insulation, but the point of the screw will penetrate through and make contact with the wire. Then by the use of properly insulated cutters a man can cut loose any wire that is liable to give trouble. We have done it in quite a number of cases in Philadelphia. We cut the wires so there is no possible danger to the firemen. The firemen understand this thoroughly. They know if they come to a fire in which a wire is passing in front of a building or into a building, as a rule, the foreman of the hook and ladder company will ask me if everything is all safe. A man is generally on duty who stays by the hook and ladder companies, so they know where to pick him up at any time. The firemen have orders from the chief of the department to allow any of the electric light people, to ride upon the apparatus if it becomes necessary to get to the fire quickly.

Secretary Garratt then read the report of the committee on state and municipal legislation, which was as follows :—

REPORT OF THE COMMITTEE ON STATE AND MUNICIPAL LEGISLATION.

For the sake of convenience and brevity, this committee recommends that its name be changed from "The National Committee on State and Municipal Legislation" to "National Committee on Legislation." The present membership of the committee is as follows :—Alabama, no member ; Arkansas, no member ; California, George H. Rowe ; Colorado, C. H. Smith ; Connecticut, John C. English ; Delaware, no member ; District of Columbia, Allen R. Foote (chairman) ; Florida, no member ; Georgia, H. E. Palmer ; Illinois, C. H. Wilmerding ; Indiana, John Caven ; Iowa, no member ; Kansas, L. A. Beebe ; Kentucky, no member ; Louisiana, no member ; Maine, Wm. R. Wood ; Maryland, J. F. Morrison ; Massachusetts, F. A. Gilbert ; Michigan, J. E. Lockwood ; Minnesota, no member ; Mississippi, no member ; Missouri, Joseph Corby ; Montana, no member ; Nebraska, no member ; Nevada, no member ; New Hampshire, Alonzo Elliott ; New Jersey, Henry W. Pope ; New York, E. A. Maher ; North Carolina, D. A. Tompkins ; North Dakota, Vincent S. Stone ; Ohio, Chas. R. Faben, Jr. ; Oregon, P. F. Morey ; Pennsylvania, A. J. De Camp ; Rhode Island, Marsden J. Perry ; South Carolina, George B. Edwards ; South Dakota, no member ; Tennessee, no member ; Texas, no member ; Vermont, M. J. Francisco ; Virginia, no member ; West Virginia, John B. Gardner ; Wisconsin, S. S. Badger ; Washington, no member.

A persistent effort is being made to complete the membership, so that every state shall be represented. It is hoped that a leading central station man in each of the states not represented will soon be found who will qualify as a member of the association, if not already a member, and accept an appointment as the representative of his state on this committee. The assistance of every member of the association, and of all others interested in its welfare is solicited, to secure this consummation.

Electric Executions.—The resolution adopted at the tenth semi-annual convention, directing this committee to use its efforts to secure the repeal of the electric execution law in the state of New York, has not been acted upon. The committee thought it best to make no move in that direction while the question of the constitutionality of the law was undetermined. While re-affirming our belief that the law should be repealed, we are of the opinion that if it is to be enforced, it should be done in the most effective and humane manner. That the law may be so enforced, we believe it necessary that it be so amended as to require a special apparatus to be devised for the purpose, that shall generate a current of not less than 10,000 volts. In this behalf, this committee recommends the association to instruct it to co-operate with the New York State association in securing such amendment of the law.

State Associations.—Since the tenth semi-annual convention this committee has engaged in the work of promoting the organization of state associations. The reason for this action is based on the fact that all legislation affecting the interests of central station companies, is either state or municipal. A state association is necessary in order to provide a medium through which the central station companies doing business in a state can act to accomplish a purpose in which they have a common interest. As there is no uniformity in legislation as between states, state associations are necessary to enable the national association to carry out the "plan of work" adopted for this committee in the most effective manner. Through the grouping of central station companies into state associations, and of state associations into the national association, the full strength of the prestige and influence of the entire industry of the country can be brought to the support of any state association or of any central station company needing assistance.

In pursuance of this policy, state associations have been organized in the following states :—

Massachusetts, Maryland, including the district of Columbia Connecticut, Rhode Island, New Hampshire, Maine, Michigan, Illinois, New York, New Jersey.

This work will be continued until all the states are organized. Membership in these associations is confined to central station companies doing business within the state. Any such company may become a member and be represented in the meetings of the state association by any one or all of its officers or employés, one of their number being designated to cast the vote of the company at the meeting.

While subjects of legislation have been the exciting cause for these organizations, it is expected that in the course of time the development of the work that may be accomplished through them, will render the legislative feature of the least importance or benefit. The improvements in electrical business methods that can be initiated or perfected through the bringing together of those having a common interest in such subjects cannot well be overestimated.

In view of the number of state associations now organized, and the prospect of the organization of a number of additional states in the near future, this committee recommends the association to instruct it to report for the action of its next convention, such changes in the constitution as will, in its opinion, best provide for the membership and representation of state associations in the national association.

Dangers to Investments in Central Station Companies.—Closely allied with the subject of legislation is the subject of the business methods by which manufacturing companies seek to make sales of their apparatus. As this committee was created for the purpose of instituting measures for the protection of the capital invested in electrical central stations, it considers the subject of the competition of manufacturing companies with central station companies for public lighting contracts, to be a most proper subject for the consideration of the association.

Within the last six months every dollar invested in electric central stations has felt the depreciating influence of an excited and misinformed public opinion. From such a cause these investments must continue to suffer until the means is found of furnishing the public with information that it can accept as being reliable, impartial and authoritative. While the damage done in this direction is great, it is not vital. The evil can be corrected.

Of a different character is the damage done to central station investments by those manufacturers who have, either openly or under cover of other names, sought to create a market for their apparatus by underbidding an established local company in its proposal for a public light contract. A low bid for public lighting is invariably used as a means of obtaining a franchise and the right to do business in a city or town in opposition to an existing company. Manufacturers have acquired their power to do this through the wealth and prestige they have gained by supplying existing companies with their apparatus. No demand can be more just this: "The value of investments in electrical apparatus and construction that have been made on the basis of manufacturers' representations of earning capacity must not be depreciated by the cutting of prices, by or through the assistance of manufacturers."

This evil is vital. In destroying the profits of the business, the reason for its existence is destroyed. It is folly to discuss the mechanical or electrical efficiency of a plant, if its financial efficiency is to be destroyed by cutting the price to be received from the service it is to render, to a point which destroys all possibility of securing a fair profit for the use and risk of the capital invested in it.

For the correction of this evil the association must rely upon the work to be done by the co-operation of all central station companies to secure reasonable legislation and just conciliation.

DISCUSSION.

It was voted to take up the report by sections. On the matter of electrical executions the discussion was as follows:—

Captain Brophy—As this resolution reads, it means nothing. "A current of 10,000 volts," is meaningless and the statement could be used greatly to our disadvantage by interested parties.

Mr. Garratt—I was about to speak on that point. Electricity may kill people in two ways, by nervous shock or by cooking. If this is to be adopted, I would suggest two things: First, that in speaking of a current of 10,000 volts, these words be added, "If the machine be devised to deliver an alternating current, the pressure of that current shall be considered equal to the heating effect in a thin wire or carbon filament under a pressure of equal potential." That prevents this being thrown out on technicality. I would also add that this machine deliver through 2,000 ohms of resistance, not over two amperes nor less than one. That will kill a man in accordance with our ideas of humanity. A 10,000-volt machine might be devised which would be equal to the tortures of the inquisition multiplied by a great many powers.

Mr. Lockwood—I move that the recommendation read that special constant potential apparatus be devised to furnish a current of not less than 10,000 volts potential and capable of delivering not less than 20 amperes.

Mr. Faben—The committee did not feel that it was part of its province to specify a bill for passage by the New York legislature. The suggestion was simply made that the voltage be placed high enough to represent a blow and not a burn.

Mr. Perry—It seems to me that it would be better to let the state take care of that matter. The fact is, that the law has been adopted by the state and stands, and for political and other considerations it will stand, and it is impossible to procure enough votes to repeal it, and if you did so, you would be obliged to pass it over again. We want, if they are going to use electricity, to make a machine strong enough to kill and not have odium attached to an ordinary machine. I do not think we ought to say anything about alternating or direct currents.

Mr. Garratt—I withdraw my whole recommendation.

Mr. Lockwood—I move to amend by adding the words, "and capable of delivering a quantity of current unquestionably sufficient to kill."

Captain Brophy—With one ampere of current and 10,000 volts it is a good deal like killing a mosquito with a ten-ton hammer, to attempt to execute a criminal. If you take any notice of this at all, it seems to me you are putting yourselves in the position of killing a fly with a club, by recommending the adoption of special devices for killing criminals.

Dr. Mason—I like what Captain Brophy has said, but I hope that if they will use electricity for this purpose they will do it by machines specially devised for the purpose of killing and not for light.

Mr. Perry—This committee had in mind the very thought which Dr. Mason has expressed. I am here as the exponent and champion of no system. The fact that the state of New York had adopted certain machines to do this work, would be a serious disadvantage to that particular make of machine. Make the law state that it shall be 10,000 volts, and then that cannot be trifled with, for no executioner acting under the law would dare to announce that he had fulfilled its mandate in any other way except as provided by the statute. That is what we had in mind. If we leave this open they will construct a machine of such voltage as they choose, and they can come out and strike the very blow from their special machine that they originally meant to strike by securing an ordinary standard commercial machine. With that change we are in a position to relieve any electric lighting company from the odium of furnishing an ordinary instrument of execution for criminals. I hope this section will stand as it has been presented with the simple amendment, if Mr. Lockwood desires to add it, of a quantity of current that will insure the desired result beyond a question.

Mr. De Camp—I think Mr. Perry expresses very clearly the sentiments of the whole committee and the idea that it had in making that report. We cannot alter the law. The committee which has had the matter in charge, find that there is a strong tendency to keep it on the statute book; electric execution must be the law of the state of New York. A bungle of an electric execution, or one or two of them, means the repeal of that law just as sure as we are here to-day.

Dr. Mason—Can't we work just as strongly without any action on the part of the association? Do the committee need our action?

President Weeks—I will say that that matter was presented in strong language to the authorities in the state of New York on former occasions, and my idea in raising this point was, that the action of this association, which is a semi-scientific body be not unscientific; it seems to me that this section can, by a very simple amendment, be made to meet all the requirements. The committee thought it should receive some support.

Mr. Perry—I think there is something here to guard, and that is the interests of electric lighting throughout this land. No one can deny that it is important, if possible, to draw a broad line between the killing machine and the commercial lighting machine. The committee arrived at the conclusion after a very careful examination, that we cannot stop the action of the law, but the next best thing is to so far relieve commercial apparatus from the odium of being used for that purpose.

President Weeks—I wish to say that a few months ago I visited Mayor Maher, of Albany, who was the chairman of the committee appointed at our last convention to present this matter to the governor of New York, with a view of finding out what had been accomplished and what might be done. He told me that he had seen Governor Hill and the latter had expressed himself very positively against doing anything in the line of the petition which we had submitted to him. I then suggested to Mr. Maher that in order to relieve the commercial apparatus and avoid any strife between commercial interests, a recommendation be made to the authorities that special apparatus be devised upon the specifications of some eminent scientist who had no connection whatever with any commercial interest. Mr. Maher said that he thought something could be accomplished in that line, and that he had no doubt that if that line was followed up properly the desired result could be reached. While I have heard nothing from him on this subject I understand from the chairman of this committee that this matter has been followed up and that they have hopes of accomplishing by this means the desired results. I only want to have the action of the convention go out as technically correct.

The motion of Dr. Mason to adopt the section as read was then put and unanimously carried.

The reading of the report was then continued, and upon its conclusion Mr. De Camp moved the adoption of the recommendation to appoint a committee on revision of the constitution and on the formulation of by-laws. The motion was adopted.

The whole report of the committee was then adopted.

REPORT OF THE EXECUTIVE COMMITTEE.

Mr. Gerald W. Hart then read the report of the executive committee as follows:—

The executive committee has confined its work largely to the present convention; other matters connected with the association having been delegated largely to special committees. The following committees have made reports at this convention, and the reports have been accepted and spread upon the minutes: Committee on underground conduits and conductors, E. T. Lynch, Jr., chairman; committee on harmonizing electric light and insurance interests, P. H. Alexander, chairman; committee to confer with Mayor Grant in regard to the International Exposition of 1892, Dr. Otto A. Moses, chairman; committee on electrical data, A. R. Foote, chairman; committee to memoralize Congress on the abolition of custom duty on copper, C. A. Brown, chairman; committee on standardization of potential on electric street railways, E. T. Lynch, Jr., chairman; the national committee on state and municipal legislation, A. R. Foote, chairman.

The work upon which these committees have been engaged is of great importance to the association, and the reports show that the subjects entrusted to them have been carefully considered, and a great amount of work has been accomplished. The secretary informs us that the number of communications from these committees which have gone out to the electrical public exceeds 12,000.

The following committees have not reported: Committee on patent legislation, Arthur Steuart, chairman; committee on electrical execution, E. W. Maher, chairman. Owing to the fact that the members of the executive committee are so widely separated, but one meeting has been held prior to the present session, since the Niagara Falls convention, although the members have been in constant communication.

At the above-named meeting held at New York on October 25th, the date of the present convention was decided upon, and a general programme was outlined; also an important resolution upon the compulsory use of underground system for high potential circuits was passed.

The finance committee, a sub-committee of the executive committee, has audited and approved the accounts of the treasurer. A committee on credentials has been appointed for the purpose of examining the credentials of the active members.

The finances of the association have never been in better condition than at present, or the future more promising. The experiment of the past year of having the head-quarters of the association at New York, has proved to be an entire success.

Since the last convention there has been a net gain of 61 members; the total membership being now over three hundred. At a recent meeting the following names were unanimously recommended for honorary membership in the association, agreeably to the constitutional provisions therefor: See article 3, section 4, Sir William Thomson, Professor Henry A. Rowland, Chas. F. Bush, Thos. A. Edison, Professor Elihu Thomson, and Frank J. Sprague.

The report was then voted upon by a standing vote and unanimously adopted.

The association, on motion, then adjourned until 3 o'clock p. m.

FRIDAY AFTERNOON'S PROCEEDINGS.

The announcement that an exhibition of the phonograph would be given and that a phonograph speech by Mr. Edison was on the programme, attracted a large audience to the Coates Opera House. The convention was called to order at three o'clock. President Weeks called upon Mr. Marsden J. Perry, the new president. He was received with cordial greetings.

ADDRESS OF MR. PERRY.

I am deeply sensible of the honor which you have conferred upon me, by electing me as your president. I know at our convention in Chicago, there seemed to be a critical moment, a year ago, when a strong man, and a true one, was needed for the position of president of this association. Then it came to me on the instant that we had with us at that time the very man; a man of scholarly tastes, exceptional business ability, sound scientific acquirements, and the necessary firmness for an executive officer. His name was Edwin R. Weeks, of Kansas City. Mr. Weeks accepted the honor, and I assure you that when he did so it took considerable courage. Out of some confusion has arisen the present occasion, our annual convention, by all means the most successful, the most instructive one that we have ever held. We have assembled here to discuss the topics of interest to us. We have now about concluded our labor, and shall return to our toil. I wish to thank you in behalf of the National Electric Light Association for the wealth of hospitalities which we have enjoyed here in your city and at your hands.

You, Mr. President, have nearly finished your official course, and are about to lay down the duties and responsibilities—responsibilities, sir, in the acceptance of this office of which I am not unmindful. But in separating yourself from the office, you leave this association under a debt of gratitude and obligation that it will take long to repay. You take with you into your unofficial life, a bond of sympathy, a warmth and depth of feeling that will not soon be broken, marred or forgotten.

Gentlemen of the convention, the grand results which have been achieved from so small a beginning, have not been accomplished by a single hand. It has only been by united effort, and I shall rely on you during the coming year for a strong united effort as well as on your indulgence with me, that we may repeat again, if possible, the glorious record of the past year.

President Weeks then introduced Mr. E. H. Johnson who made a felicitous and inimitable address. He described to the convention and the large audience of citizens of Kansas City, the principles and history of the phonograph. He was particularly happy in telling of his early association with Mr. Edison, and in describing the various steps leading to the development of the phonograph as exhibited on the stage behind him.

At the conclusion of Mr. Johnson's address, the phonograph was brought into action, and after reproducing several cornet solos by Levy, it presented the following message from Mr. Edison:—

"Kansas City, Mo.

"My Dear Mr. Weeks:—

"When I had the pleasure of meeting you at my laboratory in December last, you suggested that I should send to the Kansas City Convention, which commences next week, a phonograph discussion upon the subject of my five-wire system of distribution, which you were good enough to assure me would prove of interest to the delegates, and ever since that time I have been trying to find an opportunity to prepare the data.

"My failure to do so has been through no fault of yours, as your letters have constantly kept the matter before me, nor has it been through want of inclination on my part that I am obliged to substitute this explanation.

"Certain urgent matters of business which I was unable to anticipate have occupied my attention to such an extent that I have even had to neglect the important work of my experiments.

"While I could not have contributed to the success of the convention, which is already assured through its location in your enterprising city, I regret that I am unable to send something which would at least be more interesting than this apology.

"Yours very truly,

"Thos. A. Edison."

After Mr. Edison's message had been enthusiastically received by the audience, the phonograph was again started up, treating the house to a xylophone solo with piano accompaniment, to the great enjoyment of all present.

"PARALLEL" COMPETITION.

The business of the convention was then taken up, and the following was offered by Mr. De Camp:—

Whereas, more than $100,000,000 have been invested in central electric light companies in America, and, *Whereas*, the stocks and bonds of these companies have been and are being depreciated and jeopardized by a reckless and disastrous competition, encouraged and fostered to a large extent by rival parent companies; and,

Whereas, this course of conduct threatens the destruction alike of central station companies and of parent companies, the profitable continuance of whose business depends upon the healthy life of the central station companies, therefore,

Resolved, that the National Electric Light Association appoint a committee of seven whose duties shall be to devise and execute plans for the prevention of the evils referred to, and,

Resolved, that the president appoint this committee, and that any vacancies occurring be filled by the incoming president.

The resolutions were supported by Dr. Mason, of Boston; Mr. Armstrong, of Camden, N. J.; Mr. Lockwood, of Detroit, and Mr. Francisco, of Rutland, Vt., and were unanimously adopted.

The chair announced the appointment of the following committees:—

On underground conduits and conductors—J. E. Lockwood, of Detroit; C. H. Wilmerding, of Chicago; Schuyler S. Wheeler, of New York; T. C. Smith, of Philadelphia, and David E. Evans, of Baltimore,

On revising constitution and by-laws—Dr. A. F. Mason, of Boston; A. J. De Camp, of Philadelphia; E. A. Armstrong, of Camden, N. J.; M. J. Francisco, of Rutland, Vt., and E. R. Weeks, of Kansas City, Mo.

On relations between parent and sub-companies—Marsden J. Perry, of Providence, R. I., chairman; J. A. Morrison, of Baltimore, Md.; J. E. Lockwood, of Detroit; Gilbert, of Boston; E. A. Armstrong, of New Jersey, and E. R. Weeks, of Kansas City, Mo.

Mr. George Cutter presented the following resolutions which were unanimously adopted:—

Whereas, It seems desirable that underwriters' rules governing the installation of electrical apparatus for light and power should be the same throughout the country, and that they should be as plain and concise as would be consistent with their efficiency, and

Whereas, In order to secure the formulation and adoption of such rules it seems necessary that the authority be vested in a committee composed of representatives of all parties interested; therefore, be it

Resolved, That the chair select and appoint a committee of five members of the National Electric Light Association, who shall have power to choose three representative electrical men to act on a committee for the purpose of devising and adopting national insurance rules, and considering any other matters affecting the joint interests of insurance and electrical companies, and be it further

Resolved, That the committee of five be requested and authorized to negotiate with the various general insurance organizations throughout the country with a view to securing the appointment by them of representatives on a national electric insurance committee, and that the committee of five report the result of its deliberations and actions at the next meeeting of this association.

Dr. Mason—I wish to introduce a customary resolution, which most fitting on this occasion. I move that the National Electric Light Association express to the people of Kansas City generally, to the railroads, the surface roads, the local reception committee, the transportation committee and all others who have extended us special courtesies, our heartfelt thanks as an evidence of our appreciation of all their generous treatment. I might add very much more, but no words that I could use would more clearly express my deep sense of appreciation of their kindness.

The resolution of thanks was adopted unanimously by a rising vote.

Secretary Garratt announced the reception of a letter from the chairman of the trustees of Guthrie, Oklahoma, inviting the association to visit that city.

Dr. Mason suggested that the association intrust Secretary Garratt, if possible, to visit Guthrie and express to the citizens of that city the good will of the association, taking with him any members who wished to accompany him. The motion was carried.

Secretary Garratt—I have one other letter, in reference to which I came very near violating my duties as secretary, which requires me to bring all matters before the convention. I am quite impressed by the effect the National Electric Light Association has produced upon the western people, as appears by a letter addressed to the association by a lady who informs me that she is an eminently respectable, minister's wife, and she encloses a dollar and a half and wants us to forward to her a pair of electrical corsets. (Laughter and applause.)

Dr. Mason moved that the secretary be instructed to grant the lady's request, which motion was carried by a unanimous vote amid much laughter and applause.

Chairman Weeks then said: "As we have finished our business, I now declare this convention closed."

PLEASURES OF THE CONVENTION.

Kansas City's hospitality will be long remembered by all who attended the convention. Her people entertained the visitors with open hearts and hands in truly western fashion. A numerous and well-organized reception committee met the special train on its arrival Tuesday morning with carriages in waiting to convey the travelers to their hotels, where all hands were comfortably bestowed without delay. Those of the visitors who were strangers in the city had opportunity for a stroll of an hour or two before the assembling of the convention at noon.

The Commercial Club, of Kansas City, gave a reception to the association Tuesday evening, at their handsome and commodious rooms in the New York Life Insurance Co.'s building. Toothsome viands and excellent punch graced their table, and were not slighted by the guests.

Cordial good fellowship was established at once. The Commercial Club comprises in its membership the leading business men of Kansas City. The honor and pleasure of meeting them in their chosen resort was highly appreciated and enjoyed by the members of the Electric Light Association and their friends.

The president of the club, Mr. F. A. Faxon, pleasantly welcomed the guests in a brief address. Among other good things, he said:—"We are always glad to meet those who are carrying on the world's great work. When we begin to realize what has been done in electrical science since Franklin's time, we are almost bewildered. Among the treasures of science none are more precious than those which have been obtained by those who have learned to control the lightning. It is a pleasure, therefore, for us to have such a distinguished body of scientists meet in our city.

"We have a city here which in its hustle and growth is perhaps without a parallel in the country. You must remember we are young. By the side of the buildings which tower to the sky are still to be seen the cabins of the pioneers, and the pioneers are still with us. In building up the city we want the best, and if you have the best then we want to buy it."

President Weeks happily expressed the acknowledgments of the association for the courtesies of the club.

The remainder of the evening was spent in informal conversation, many pleasant introductions of visitors and hosts, many of which will doubtless lead to future renewals of acquaintanceship so agreeably begun.

President Weeks and Mrs. Weeks paid a graceful compliment to the members of the association by going out over night to Kearney, 30 miles from Kansas City, and boarding the special train there Tuesday morning, making the last hour of the journey with the delegates and their friends on board.

Thursday, February 13, Mrs. E. R. Weeks and Mrs. F. B. Tiffany gave lunch parties to the ladies attending the convention. Thursday evening Mr. and Mrs. Weeks gave an informal reception, at their house, to the gentlemen of the convention.

An extremely enjoyable excursion was made Wednesday, February 12. By invitation of the Chicago, Milwaukee & St. Paul Railway Co., and the Excelsior Springs Hotel Co., the delegates and their friends were conveyed to the Springs by a special train, and were there entertained at dinner by the hotel company. The visitors were unanimous in their admiration of the Excelsior Springs establishment and in appreciation of the lavish hospitality of the hotel company.

A delightful break in the journey to Kansas City was made at Chicago. On the invitation of the Chicago Electric Club the afternoon of Monday, February 10, was devoted to a "stop over," and the enjoyment of a reception and lunch at the club rooms. Members of the club were out in force at the Union depot on the arrival of the "electric limited." They took possession of the company from the train, who were driven directly to the club rooms. Special provision was made for the comfort and entertainment of the ladies of the party. After an hour or so of informal sociability, meetings of old friends and the acquisition of new ones on both sides, the entire company assembled in the large hall of Kinzey's, where an elegant lunch was served. Mr. F. G. Beach briefly but heartily welcomed the visitors from the east and north, and introduced Mayor Cregier, who addressed the assemblage in behalf of the city of Chicago, bidding all to make themselves at home, to remember that Chicago and New York were sister cities, alike in many respects, particularly in their common desires towards the forthcoming world's fair. In behalf of the guests, brief remarks in acknowledgment of the courteous attention of the day were made by several of the eastern delegates. After the reception the visitors separated, many of them spending an hour or two in seeing points of interest conveniently accessible in the city, under the guidance of members of the club, all of whom were unremitting in their attentions till they bade good-bye to their guests as the special train rolled away for Kansas City at five o'clock.

COLLEGE NOTES.

Harvard University.

The freshmen lectures on physics began Thursday, February 20. They will be eight in number, given by Professors Trowbridge and Hall. These lectures, although primarily intended for freshmen are open to all members of the University, and several of the upper classmen have expressed the intention of attending regularly.

At the Cambridge manual training school, by a special arrangement between the University and the directors of the school, a number of Harvard men receive instruction in shop work. The school was established by the generous donor of the new Public Library and new City Hall of Cambridge, Mr. Ringe, of California. On the ground floor are two large rooms, one for wood work, the other for metal work. Between them is the forge and boiler room. Both departments are fitted up with machines and tools of the latest types. Power is furnished by a Brown engine. During the Christmas recess the students wired the building for incandescent lamps, under supervision of an expert. A 200-light Thomson-Houston dynamo is to be installed.

Mr. H. S. Wilkinson, '91, has been elected secretary of the Electric Club in place of S. K. Perot, L.S.S., who resigned on account of pressure of other duties.

February 26, Mr. C. H. Davis, of New York, who is a nephew of Professor Davis of the scientific school, will give an informal talk before the Electric Club on "Practical Electrical Engineering." On the 12th G. T. Page, '92, spoke on "Steam Engines used in Electric Lighting." The talk included an explanation of the leading types of stationary engines, and was illustrated by a number of photographs and charts.

Professor B. O. Pierce, of the Physics department, is seriously ill with a slow fever, brought on by overwork. He will be unable to resume his work for some time. Professor Pierce is very popular with the students, and has the sincere wishes of all for his speedy recovery. At last accounts he was gaining, though very slowly.

In physics 4 (electrodynamics) a new method of laboratory work will be employed during the last half year. The students are divided in pairs, and to each pair is assigned an experiment—Weber's determination of the Ohm, for instance. The men are expected to work out the experiment themselves by consulting the best works on the subject, and devising arrangements of apparatus. The instructor and assistant are always ready to answer questions or give advice, but the student is expected to rely on himself as much as possible. At the conclusion of each experiment a written report is to be submitted. This method is similar to the one employed at the German laboratories.

The Electric Club has lately received a number of handsome photographs of the Ball engine, also large charts and engravings of the Hamilton-Corliss engine, and blue prints of the Harrisburg Ide engine; also a treatise on the Porter-Allen engine, and a number of fine catalogues of the Buckeye A. & S., Straight Line, Watts-Campbell, Reynold-Corliss and Russel engines, and a large chart of the Jarvis furnace. More are to follow, and the club expects to have as fine a collection of descriptions of leading engines as can be found anywhere.

Cornell University—Sibley College.

Several important additions have recently been made to the material equipment of the department of electrical engineering and physics. Four small Edison dynamos, each of 250 Watts capacity, have been purchased by Dr. Thurston. They will be used entirely for experimental purposes. A Westinghouse 650-light alternator has been exchanged for a Stanley alternator. This machine is furnished with two armatures, one of which regulates for constant current, the other for constant potential. Tobey and Wallbridge, '90, will make a study of this new machine in their thesis work. The Westinghouse Electric Co. are also constructing a small alternator which will be used for experimental purposes.

Two Sprague 10 motors will soon be added to the department. Twelve sensitive galvanometers are being constructed in the department of physics for use by the Juniors in their laboratory work. The coils of these instruments are interchangeable and vary in resistance from 0.1 to 10,000 ohms. An improved Poggendorf switch, designed by Professor Moler has been placed in the laboratory. This switch is run from the line shaft and by means of cone pulleys 9 speeds, giving alternations varying from 3000 to 36000 per minute, may be obtained. It is used for the calibration of alternate current ammeeters and voltmeters. By means of two sets of brushes sparking is reduced to a minimum, a current of 10 amperes being alternated with no serious effects from that cause. L. B. Marks, R. G., has designed an alternator which will be constructed by the department of physics. The machine is of the mordey type, and has a capacity of 200 volts and 10 amperes. It is also designed to be used as a synchronous motor, its exciter being so made that it can be used for starting the motor from an alternating circuit. Mr. Marks proposes to make a study of the machine for a thesis, making a comparison of the theoretical with the actual results obtained from the machine. It is proposed to construct a number of transformers, varying from 5 volts and 400 amperes up to 10,000 volts and a fraction of an ampere, which are designed to be used with the alternator.

A small electric lighting station is in successful operation in the mechanical laboratory. The work of the seniors in that department consists of complete efficiency tests of the entire plant from the coal pile to the arc light.

The Senior Electrical Engineering Association organized at the commencement of the college year, has held a series of interesting and successful meetings during the present term.

The following papers have been read :—

F. N. Waterman, '89, "Practical Experience with Arc Lighting;" J. W. Cowles, '90, "The Thomson-Houston Railway System;" Professor A. S. Hathaway, "Molecular Dynamics;" Professor E. L. Nichols, "Historical Sketch of the Theories of Magneitsm;" A. H. Herschel, '90, Electric Railway Signals ;" J. E. Greenwalt, '90, "Practical Experience with Incandescent Lighting ;" W. B. Tobey, '90, "Methods of Wire-Drawing and Annealing;" Professor F. Osborne, "Building Materials for Electric Lighting Stations ;" Professor H. J. Ryan, "History of the Atlantic Telegraph." Professor Nichols is delivering lectures this term on the "Mathematical Theory of the Dynamo." This course of lectures will be followed by another course on "Photometry in Relation to Electric Lighting." Professor H. J. Ryan is giving a course of lectures on "Design of Alternators and Transformers." Under his direction the work of Seniors for the present term in the draughting-room consists of the design of continuous current generators and motors, alternate current generators and motor, open and closed circuit transformers.

Mr. E. G. Merritt, instructor in physics is giving, an electric course of two hours per week in the "Mathematical Theory of Motors, Alternators and Transformers." S. C. Thompson's Dynamo-Electric Machinery is used as a text-book.

On Feb. 21, Professor Alexander Graham Bell, one of the Sibley non-resident lecturers, delivered an illustrated lecture on "Radiophony." The lecture consisted of an historical sketch of the invention of the radiophone and its subsequent improvements. The apparatus used in the lecture has been presented by Professor Bell to the college,

The annual inspecttion tours of the mechanical and electrical Engineering students have been so successful and profitable that an increased range has been given to the tour of 1890. The programme includes itineraries, east, west and south, the classes being divided into three sections. The routes have been very happily arranged by Dr. Thurston to include typical establishments and installations in the several regions to be visited. The tours will begin March 20.

THE LOW TENSION BILL DEFEATED IN VIRGINIA.

The first serious attempt to limit by legislative action the voltage of electric currents employed in the distribution of light and power as originally recommended by Harold P. Brown, and endorsed by Mr. Edison in his article in the *North American Review*, has been made and has failed. About the first of February, Senator Lovenstein introduced a bill into the Virginia legislature "for the prevention of danger from electric currents." The bill was referred to the committee on general laws, who gave a hearing to parties interested on the evening of February 11, at which both the advocates and the opponents of the bill mustered in force. The most important provision of the proposed act is contained in the following extract :—

> In all electric circuits or parts of circuits, whether they be in whole or in part under or above ground, the electric pressure used shall not exceed the following amounts : The non-pulsating continuous current to a pressure not exceeding 800 volts ; the pulsaling continuous current to a pressure not exceeding 550 volts : the alternating current to a pressure not exceeding 200 volts, according to the nature of the current used.

An announcement that Mr. Edison himself would attend the hearing and speak in advocacy of the measure attracted a large audience.

Senator Lovenstein said he had introduced the bill at the request of several of his constituents and that his sole object was to protect property and persons from danger. The bill was introduced in the interest of no one concern or monopoly, but for the public weal. He then introduced Mr. Boulware the attorney for the Edison company, who said that the great loss of life and destruction of property by electricity was what impelled the gentlemen whom he represented to ask for the passage of the measure. He was present in the interests of the public. Electricity was one of the greatest of powers, but exceedingly hard to manage, and less was known of it than any other agent of force. The public alarm had now become so great that unless increased safeguards were thrown around the management of the wires electricity would have to be abolished. Everybody was apprehensive, and there was a general clamor that the electric current should be made safe. His clients asked for no monopoly. It was merely proposed to fix a limit within which all companies may operate without danger, and without changing their system. Mr. Boulware then introduced Mr. Edison and Mr. Harold P. Brown, stating that one was the "father of electricity," and the other an "electrical engineer of distinction."

Mr. Wyndham R. Meredith then took the floor and outlined the opposition to the bill. After paying a graceful compliment to Mr. Edison, he went on to say that he could not see why gentlemen from New York, unacquainted with the surroundings, should trouble themselves to come to Richmond to look after a matter that was wholly local in its bearings. He believed this bill had been prepared in behalf of some special commercial interest rather than the safety of the people. No one in Virginia had been hurt by electricity so far as he knew, and in any event he thought the passage of this bill would tend to increase rather than lessen danger. He said he represented the Schuyler company and the Virginia Electric Light and Power Co., both of which, if this bill became a law, would have to go out of existence.

Mr. Edison's remarks, which followed next, were in the form of answers to previously prepared questions asked by Mr Boulware, and these were ingeniously devised to bring out only such points as would forward the proposed legislation. Mr. Edison said that all that was needed to enable all companies to use a safe system of arc lighting is a small expenditure of money. He said emphatically that the charge that the intent of the bill was to press out other companies than those operating under the Edison patents was utterly untrue. "Other companies will not be driven out of the field" he declared "but let them conform their system to ours." While speaking, Mr. Edison put his hand in his pocket, pulled out a piece of paper, and said that while he considered the bill a reasonable and proper measure he would like to suggest an amendment to it. He then read from the paper the following :—

> After the passage of this act it shall not be lawful for any individual or corporation, public or private, to generate or use or cause to be used for distribution to the public, directly or by induction, any electric current with sufficient electric pressure to produce human death accidentally by the direct action of such current.

The committee looked at each other in some surprise at Mr. Edison's somewhat unusual proposition to amend a bill pending before the legislature.

A number of the committee asked what changes would be necessary in existing plants and what would be the cost.

"Well," said Mr. Edison, "for a town of about 5,000 inhabitants, say Lynchburg for instance [great laughter], about $10,000 or say 10 or 12 per cent."

Mr. Edison said he had no patent, either on high or low pressure. Through the persuasion of his partner he had bought indeed a system a few years ago (referring to the Zipernowski-Deri system), and subsequently felt like putting a skull and crossbones or white cap's notice on the shield.

Mr. Harold P. Brown next addressed the committee and in half an hour's speech gave a full account of himself and his discoveries. He thought it would be better to have no specific limit to the voltage mentioned in the bill, the better way being to test everything by "trying it on a dog." He closed with a lengthy citation of alleged instances of deaths from electricity in various parts of the country.

Professor Henry Morton was next introduced, who, after a clear but brief explanation of the peculiarities of the several different forms of electric current mentioned in the bill, addressed himself to the statements made by his predecessor.

All that Mr. Brown has said about electric currents," said Professor Morton, "has been known for 25 years. There's nothing new about that. Nobody pretends that the alternating current is safe. At high pressure, with less volts, it will kill quicker than any other. But it is not a question of having a system that is absolutely safe. A railroad train that runs 40 miles an hour is less dangerous than one at 60 miles an hour, and one at 20 is safer still, and at six miles an hour it is far less dangerous, but on that account are you going to give up railroad traveling? Kerosene lamps are dangerous, but are you going to give them up because every few days one explodes and somebody gets killed? Street cars are dangerous, and so are hundreds of other every day conveniencies I might name, but are you going to give them up on that account? If you are, you might as well go back to barbarism. So you see it is not a question of getting something that is absolutely not dangerous, but only for surrounding dangerous things with proper precautions. Steam boilers have often killed people, but nobody says turn out the boilers. The idea instead was to construct them that they could carry a high pressure of steam, and those that carry the most pressure are the strongest. He thought that the bill before the committee, if passed, would require the adoption of Edison's patent, and oblige the other companies to pay each a royalty as to make their own business profitless.

Judge Theodore Garnett, of Norfolk, said that no accident from electricity had ever occurred in his city, but nevertheless, if the bill passed, $25.000 worth of electrical plant in Norfolk would have to go out of existence. [At this point the hearing was adjourned for the day, but was resumed next morning.] Judge Garnett, continuing, said that this bill had not been called for by public opinion in the state; that no petition recommending such a law had been presented to the general assembly by anyone, and that every practical man connected with electric interests was opposed to its passage. If the promoters as they claimed were actuated by purely philanthropic motives, why should they come here from New York and New Jersey, where persons had lost their lives owing to absolute carelessness, and endeavor to induce the legislature of Virginia to pass such a law as this, when only a single case could be brought forward where anyone had ever been injured by electricity in this state. Why not have such laws passed by the legislatures of New York and New Jersey now in session?

Mayor Ellyson, of Richmond, who spoke next, believed it unwise that such a bill should be passed by the assembly, and, moreover, asserted that the city authorities were entirely competent, and had full power to deal with the subject whenever the necessity arose.

Senator Barry made an eloquent speech in opposition to the bill which was frequently applauded, and closed by asking that the City of Liberty be exempted from the operation of the bill should it become a law.

Mr. Chamberlain, of Norfolk, spoke briefly opposing the bill.

The Piedmont Electric Illuminating Co. through its president, and the cities of Alexandria, Petersburgh and Danville through their senators also protested earnestly against its passage.

At 11.30 A. M. the committee retired to their room to formulate their report to the senate. After consideration they agreed by a vote of 11 to 0 to recommend that the bill be not passed, expressing the opinion that the subject was one which each municipal authority could most properly deal with for itself, and that no legislation on the part of the state was desirable or necessary.

MANUFACTURING AND TRADE NOTES.

THE BROWN & SHARPE MANUFACTURING CO., Providence, R. I., have been so long distinguished for the range of their production of machinery and tools of the highest class of excellence, that any mention of their merits would seem superfluous. Some of their illustrated circulars are almost as gratifying to look upon as one of their symmetrical and handsomely finished machines. The illustrated supplement to their catalogue delights both the mechanical and the artistic eyes. The engravings leave nothing to be desired in clearness and beauty, while they are sumptuously printed upon a creamy background, giving something of the effect of Japan paper.

Readers are doubtless aware that the Brown & Sharpe Manufacturing Co. received "The Grand Prize" for their exhibit at the Paris Universal Exposition of 1889.

THE POND ENGINEERING CO., of St. Louis, are prominent among similar establishments that have taken up the design, contracting and constructing of power plant for electric lighting and power stations. They make complete outfits for such purposes a specialty. Their latest circular embraces a variety of engines, boilers, pumps, and special appliances for the equipment of stations of varying requirements. The Pond company have fitted out a large number of stations in the west.

S. H. TERRY, 4012 North Grand avenue, St. Louis, Mo., has put upon the market a sheet steel pole for electric railway and electric light wires, that seems to possess merit in several particulars. It is light and rigid, and, says Mr. Terry, the most economical pole yet put upon the market. These poles are in use on Mr. John Scullin's Union Depot Electric Railway in St. Louis.

THE PHOSPHOR-BRONZE SMELTING CO., Limited, Philadelphia, original manufacturers of phosphor-bronze in the United States, have issued their Price List, No. 7, 1890. A glance at the index suffices to indicate the wide range of use already attained by their product. The metal is furnished in sheets, rods, ingots or castings. It is manufactured by the Phosphor-Bronze Smelting Co. into wire (for springs or for electrical purposes), ropes, wire-cloth, nails and tacks, rods and bolts, screws, chains, pens and tools. It is made of varying temper to suit special purposes, and has found its way into many branches of manufacture and trade where copper and brass were formerly employed.

THE GARVIN Universal Milling Machine, with its various attachments is meeting with deserved favor in many workshops. The Garvin Machine Co., Laight and Canal streets, New York, issue a special circular describing the milling machine and its accompanying devices, with prices for the several sizes manufactured. The circular contains a detailed example in bevel gear work that will be found instructive to beginners.

MR. JARVIS B. EDSON, of 87 Liberty street, manager of the Edson Pressure Recording Gauge Co., recently remodeled his offices, and has given them a very attractive appearance. He has on exhibition a large number of charts taken from his recording gauges, which demonstrate their usefulness and show that firemen take pains to keep their steam pressure steady when they know that it is being recorded. These gauges are in use in many prominent electric light stations. Two of the gauges were, not long since, installed in the new Edison station in Brooklyn, and one has recently been set up in the Denver Edison station. To these may be added the installation in the electric light plant of the Pennsylvania Railroad Co., at Jersey City, the Syracuse Heat and Power Co., the Excelsior Electric Power Co. and the East River Electric Light Co., of this city.

STREET RAILWAY NOTES.

THE THOMPSON-HOUSTON ELECTRIC CO. continue, notwithstanding the unfavorable season of the year, to start running electric railway lines that they have been constructing during the latter part of 1889. Among the roads put in operation by them since January 1 are the following:—Macon City and Suburban Ry. Co., Macon, Ga., 8 miles, 8 cars; Minneapolis Street Ry. Co., Fourth avenue, Minneapolis, Minn., 8 miles, 10 cars; Ross Park Street Ry. Co., Spokane Falls, W., 7½ miles, 10 cars; Grand Avenue Line, St. Paul, Minn., 6 miles, 2 cars; St. Louis & E. St. Louis Electric Ry. Co., St. Louis, Mo., 2 miles, 6 cars; National Electric Tramway & Lighting Co., Victoria, B. C., 4 miles, 6 cars; Doncaster and Box Hill Tramway Co., Victoria, Australia, 2 miles, 1 car.

The Thomson-Houston company have made the following recent railway contracts: Augusta, Hallowell & Gardiner Ry. Co., Augusta, Me., 3 miles, 3 cars; North Side Ry. Co., Fort Worth, Tex., 15 miles, 8 cars; Gloucester Street Ry. Co., Gloucester, Mass., 5 miles, 3 cars; Port Townsend Street Ry. Co., Port Townsend, W., 3 miles, 2 cars; Springfield City Ry. Co., Springfield, Ill., 7 miles, 8 cars; Boston Construction Co., Spokane Falls, W., 7 miles, 7 cars; Inter-Urban Line, St. Paul, Minn., 22 miles, 15 cars: Northwest Electric Construction & Supply Co., West Superior, Wis., 2 miles, 1 car; Douglas County Street Ry. Co., West Superior, Wis., 4 miles, 2 cars; Winona City Street Ry. Co., Winona, Minn., 4 miles, 5 cars.

ST. LOUIS, MO.—The Lindell street railway line, of St. Louis, Mo., where there are now 12 Sprague cars in operation, will be supplied with electric equipments throughout with the Sprague system. Double bracket iron poles placed between the two tracks will be used, and will be of an ornamental and tasteful design. Each pole will carry an arc lamp, and so will act for the double purpose of lighting the street and carrying the trolley wires.

The only wires overhead will be the trolley wires. The main feeder and arc light wires will all be carried underground.

MINNEAPOLIS AND ST. PAUL.—After a careful examination of all the systems of railway propulsion, both cable and electric, the management of the Minneapolis Street Railway Co., which controls all the street railway lines in the cities of Minneapolis and St. Paul, with an aggregate of 200 miles, has adopted electric traction, and on the 19th of February closed a contract with the Sprague Electric Railway and Motor Co. for the electrical equipment of its roads.

SOME CAR RECORDS.—When electric railways were first introduced, street railway men said that the motors were not sufficiently durable for the necessities of street car service. That may have been true then; but the durability of the electric street railway motor, as exemplified in the productions of the leading manufacturing companies of to-day, is probably as high if not higher than that of any other machine exposed to similar conditions of service.

At Erie, Pa., on the line of the Erie Electric Railway Co. one motor car has run 19,300 miles without requiring repairs of any kind. A second car, equipped with only a single motor, has run 15,000 miles without repairs, and other cars have records closely approximating the above.

The Erie electric railway has been in operation for several months on the Sprague system, and is said to be giving entire satisfaction to the managers of the road, and to the general public.

The equipment of the road is complete in every respect. At the station the power plant includes two 150 h. p. Ball engines, with 16″ x 16″ cylinders, each engine being belted directly to two 50,000 Watt railway dynamos which furnish the current to the line. There are 15 electric cars equipped with the Sprague improved motors and all the latest attachments and devices used by the Sprague company upon its cars.

CAR-HEATING COMPANIES CONSOLIDATE.

Early in February, George Westinghouse, Jr., and C. H. Jackson, president and vice-president respectively of the Standard Car-Heating and Ventilating Co., of Pittsburgh, Pa., became directors and large shareholders in the Consolidated Car-Heating Co., of Albany. The interests of the Pittsburgh company were thus consolidated with the Albany company, which, by this arrangement, greatly extends the field of its operation and becomes the owner of an additional number of valuable patents and improved devices for heating and ventilating railroad cars and for lighting such cars by electricity. Automatic regulation of heat, which will obviate the complaints of the variable temperature of steam heated cars, is also secured by an attachment to the air-brake cylinder with which all cars are already equipped. Several of the features of the heating systems of the Standard company have lately been on trial upon the Pennsylvania and the Baltimore and Ohio railroads, with favorable results.

INTERIOR ELECTRICAL CONDUITS.

On Friday, February 7, at the invitation of the Interior Electrical Conduit Co. a large company of gentlemen assembled at the works of the Bergman Electric and Gas Fixture Co. in this city, to witness some experiments designed to show the efficiency and convenience of the "interior conduit." The important departure in interior wiring introduced by the new company consists in providing a regular system of conduits or tubes within houses in the same way as pipes are employed for the distribution of gas. These tubes are made of a practically non-combustible compound, are light and moderately flexible, and through them the wires are drawn to each floor, chandelier or bracket as required. The tubes are furnished in sizes varying from ¼ to 1¼ inside diameter.

Mr. E. H. Johnson conducted the experiments with the assistance of Messrs. E. T. Greenfield and J. H. Vail, explaining the construction of the tubes, and the manner of their arrangement. The system was shown in use; conduits of various sizes being distributed about the room in which were wires feeding a considerable number of lamps.

Object lessons in running the tubes and inserting conductors were given clearly, exhibiting the simplicity of the system, and its easy application to all classes of interior wiring. Mr. Johnson described the dangers to interior wires as arising from three causes, viz: overloading, short circuits and leakage, the latter being the most dangerous and the one heretofore least guarded against. A leak might carbonize the material surrounding the wire and form a dangerous arc without blowing the safety fuses, and thus start a fire. To guard against this, the plan has been adopted by the Interior Conduit Co. of employing circuits in which the two conductors covered with good cotton insulation twisted together and covered with thorough waterproof insulation, and then braided—are carried in one tube. Thus a leak must immediately develop into a short circuit, the safety plug is blown at once, and the current shut out from the circuit. The formation of dangerous arcs through leakage is thus avoided This effect was experimentally shown the visitors.

Other equally successful experiments were made exhibiting the safeguard qualities of the tubing, as against overloading and consequent overheating of conductors.

Mr. Johnson read a report of test, made by Mr. A. E. Kennelly, at the Edison laboratory, of the insulating properties of the tubing. The report showed that a length of tubing, such as ordinarily made, gave, after three weeks' immersion in water, an insulation resistance of 15 megohms, or about 40,000 ohms to the mile. Thus, while the tubing is not relied upon for insulating the conductors it obviously affords practically absolute protection against dampness.

After the exhibition and experiments the party in attendance were handsomely entertained at the Hoffman House, where an elaborate luncheon was served.

THE EDISON GENERAL ELECTRIC COMPANY.

The following financial statement of the Edison General Electric Company, from official sources, will be of general interest. This company was organized in April, 1889, under the laws of the state of New York, for the purpose of acquiring the property, franchises and business of the several Edison manufacturing companies, and for the manufacture and sale of electrical apparatus, light and power.

The total capital stock of the company is		$12,000,000
Of which has been issued		7,612,700
Leaving in the treasury of the company		1,890,800
Of the total capital stock of the company there had been issued in exchange for stocks of various Edison companies, and to be so issued	$7,612,700	
Held in trust by Farmers' Loan & Trust Co	2,496,500	
Remaining in treasury Jan. 29, 1890	1,890,800	
	$12,000,000	

The Farmers' Loan & Trust Co. has issued its printed certificates against the above $2,496,500 of stock, deposited with them under deeds of trust, dated April 26 and December 26, 1889. Under the provisions of these trusts, the trust certificates will be exchanged for the stock deposited against them, whenever the trustees shall in any one fiscal year declare a dividend of 8 per cent. upon the entire capital stock of the Edison General Electric Co. then outstanding.

The companies which have been acquired by the Edison General Electric Co. are as follows:—

14,003	shares Edison Electric Light Co., out of 15,000 shares. Par, $100.
7,500	shares The Edison Machine Works. Entire capital stock. Par, $100.
7,500	shares Bergmann & Co. Entire capital stock. Par, $100.
400	shares Canadian Edison Manufacturing Co. Entire issued capital stock. Par, $100.
100	shares Edison Lamp Co. Entire capital stock. Par, $2,500.
13,920	shares Sprague Electric Railway and Motor Co., of which 8,720 shares were acquired since November 1, 1889. Entire issued capital stock except 80 shares. Par, $100.
1,000	shares Leonard & Izard Co. Entire capital stock. Par, $100.
5,000	shares United Edison Manufacturing Co. Entire outstanding capital stock. Par, $100.

The following statement shows the nature and extent of the business of these companies:—

Edison Electric Light Co.—This company owns all the Edison patents, and sundry other patents, for incandescent electric lighting in North and South America, and all patent litigation is conducted in its name. It grants exclusive lincenses for specified territory to local companies, receiving in payment therefor, as royalty, a proportion of all securities (stocks or bonds) issued, or to be issued, by such licensed companies. On October 31st, it held $1,749,573 of stocks and bonds of different companies acquired for such licenses. Its relation to such licensed companies is not only a stockholder, but also the grantor of a license, which it reserves the right to forfeit if its terms are not complied with. Its balance sheet is submitted as follows:—

Edison Machine Works, Bergmann & Co., The Edison Lamp Co., Canadian Edison Manufacturing Co.—The four above-named companies (owned entirely by the Edison General Electric Co) are corporations engaged in the manufacture of appliances required to furnish light and power by electricity. Their plants and output are as follows:—

Edison Machine Works.—Plant worth $1,500,000, situated on 29 acres of ground at Schenectady, N. Y., employing 1,400 men, and having a present capacity of $3,000,000 a year output.

Edison Lamp Co.—Plant worth $1,200,000, at Harrison, N. J., employing 500 men, and making nothing but lamps, of which its present capacity is 8,000 a day. It has a branch factory at Hamilton, Ont., where lamps used in Canada are manufactured.

Bergmann & Co.—Two plants worth $900,000 in the City of New York, employing 500 men, and having a present capacity of $1,500,000 a year output.

Canadian Edison Manufacturing Co—Plant worth $40,000, at Sherbrooke, Canada, employing 100 men, started in pursuance to the Canadian laws requiring all patented articles sold in Canada to be manufactured there.

The consolidated balance sheet of the four manufacturing companies abovenamed is herewith submitted.

Consolidated Balance Sheet, Manufacturing Companies, Oct. 31, 1889.

Assets.

Consolidated Ledger Accounts.	Totals.
Property accounts	$1,382,496 72
Cash, accounts receivable and bills receivable	880,031 87

LEGAL NOTES.

ELECTRIC STREET RAILWAY INTERFERENCE WITH TELEPHONE SERVICE.

A Decision in Favor of the Railways

Rocky Mountain Bell Telephone Co. *vs.* Salt Lake Street Railway Co.

In December last, at Salt Lake City, Utah, there was tried the case of the Rocky Mountain Bell Telephone Co. against the Salt Lake City Street Railway Co., in which the plaintiff sought to enjoin the defendant from operating its lines on or along certain streets in that city, parallel with the telephone wires. The case was heard before Judge Lane, of the Third Judicial District Court of the Territory.

The evidence put in by the telephone company was to the effect that the service was so greatly impaired by the interference from the single trolley system used by the railway company as to be, in the case of many subscribers, practically useless, and the defense of the railway company was that the double trolley system was impracticable on their routes, and that the adoption by the plaintiff of the "McCluer system," or, at any rate, of a metallic circuit system, would be a complete remedy for the evils complained of.

The decision of the Judge, rendered January 16, denied the prayer of the complainant for an injunction. The Court concludes as follows:—

Assuming that the use of the metallic circuit would remedy the evil complained of, and that its use was equally practicable by either party to this action, the Court will not enjoin the use of the ground circuit by the defendant while the plaintiff continues to use it. It appears from the preponderance of evidence that the use of the metallic circuit by the plaintiff is practicable; while its adoption by the defendant would be an experiment; its practicability does not appear to be established. The prayer of the complainant for an injunction is denied."

A Decision Adverse to the Railways.

Superior Court of Cincinnati.

The City and Suburban Telegraph Association, vs. The Cincinnati Inclined Plane Railway Company.

Taft, *J.*:—This is an action to enjoin the defendant from using a system of electric railway propulsion known as the single trolley system, in running its cars upon the streets of this city and the roads of the county, because, as plaintiff claims, it does a great injury to the conduct of the public business in which it is engaged, *i. e.*, the maintenance for profit of telephone communication between a large number of subscribers in the city and county. Plaintiff alleges that it has been conducting its business under lawful grants of the legislature of the state and the municipal authorities, and by virtue thereof has lawfully erected many lines of telephone wires on the streets upon which the street railway of defendant is constructed and operated. That the defendant has no lawful authority to use electricity as a propulsive power for its cars; that the single trolley system in use by defendant conducts upon and induces upon the wires of the plaintiff erected on the same streets currents of electricity, which make it impossible to use those wires for the purpose of telephone communication; that the result is, that many of the subscribers of plaintiff have made complaint and threatened to discontinue the use of the telephone, and some have refused to continue payment for the same, all to the great injury of the plaintiff; that the damage is irreparable and continuous, and that plaintiff notified defendant before the erection of the single trolley system that it would result in a serious injury to plaintiff, and of the objection to the system.

The defendant answers, denying plaintiff's lawful right to operate telephone lines; avers its own lawful right to conduct a system of electrical railway propulsion; avers that the single trolley system is the only practicable one in use, and secures advantages to the defendant not afforded by any other; that plaintiff's difficulties arise from the defects of its own telephone system, in that, for economy, it uses the earth as a return conductor, and so invites onto its lines many disturbing currents, both natural and artificial, although the mechanism of the telephone is so delicate that any proper system would make the return circuit metallic; that plaintiff's claim amounts to a claim to the exclusive use of the earth as a conductor, which is without warrant of law; that the use by the defendant of the earth as a return circuit is a material assistance in propelling cars up heavy grades; that it could not alter its system so as to avoid the use of the earth as a return circuit except at great outlay and loss of efficiency. The answer denies that the operation of its road produces interference with the telephone lines of plaintiff, and says that, if any injury has been produced for which defendant is liable, the damages are capable of exact ascertainment, because they can all be remedied by an additional expenditure by the plaintiff, and that therefore there is no ground for equitable relief.

Plaintiff, by its reply, denies the allegations of the answer.

1st. The plaintiff company was organized in 1873 as a magnetic telegraph company, to conduct a telegraph business on lines within the city and between here and Hamilton, under laws which have since been incorporated in chapter 4, title ii, concerning magnetic telegraph companies. Section 3454 provides that "a magnetic telegraph company heretofore or hereafter created may construct telegraph lines from point to point, along and upon any public road, by the erection of the necessary fixtures, including posts, piers, and abutments necessary for the wires; but the same shall not incommode the public in the use of such road." Section 3461 provides that, "when any lands authorized to be appropriated to the use of a company are subject to the easement of a street, alley, public way, or other public use, within the limits of any city or village, the mode of use shall be such as shall be agreed upon between the municipal authorities of the city or village and the company; and if they can not agree, or the municipal authorities unreasonably delay to enter into any agreement, the probate court of the county, in a proceeding instituted for the purpose, shall direct in what mode such telegraph line shall be constructed along such street, alley, or public way, so as not to incommode the public in the use of the same; but nothing in this section shall be so construed as to authorize any municipal corporation to demand or receive any compensation for the use of a street, alley, or public way, beyond what may be necessary to restore the pavement to its former state of usefulness."

In 1878 the telephone, as a practicable commercial instrument, came into use, and the plaintiff became the licensee of the American Bell Telephone Co., with exclusive right to use all its patents in this city and county. Before this time, in 1873, the Common Council had passed resolutions fixing the terms under which the plaintiff might occupy the streets with its poles. From 1878 until the present time, the business of the plaintiff has grown to such an extent that it now has over 3,000 subscribers in the city and vicinity. The pole lines of the plaintiff along the streets occupied by the defendant's railway were erected in 1881 and 1882. In 1880, the following section was added to the telegraph law, 3471: "The provisions of this chapter shall apply also to any company organized to construct any line or lines of telephone; and every such company shall have the same powers, and be subject to the same restrictions, as are herein prescribed for magnetic telegraph companies."

The pole lines of the plaintiff are so erected under the ordinances of the city as to leave a bar at the top of each pole, on which to string the wires of the fire department telephone lines. The fire department and police department are each given a separate exchange, operated by city employes. The city strings its own wires upon the telephone poles, but pays nothing to the plaintiff for the use of the instruments, or for the general exchange work of the fire and police department. The poles have been erected at such places as directed by the engineer of the Board of Public Affairs, and under his supervision. The plaintiff has always used the earth as the return circuit. This has been the case with all the telephone systems in this country down to the present day, with the exception of certain long-distance lines from New York city, and the connecting subscribers who frequently use those lines in that city. The telegraph companies have used and still use the earth as the return for the circuit. The most complicated part of the telephone business is the mechanism by which temporary connection is made between any two subscribers' lines. It is called a switch-board, and each one of the exchanges, of which there are five in this city, is furnished with one. It is a very expensive instrument, and could not be adapted to use for a system of metallic circuits.

It will thus be seen that every step taken by the plaintiff was authorized by law, and that all that has been done by it has been with the consent of the proper authorities. From this statement, there can be no doubt that the plaintiff has a lawful right to occupy the streets upon which defendant's track is laid, with the poles and wires erected for the conduct of its business, and that the use of the earth as a return is not a violation of its franchise. It was organized and still is called a telegraph company. It began its telephone business before section 3471 was passed, and perhaps some of its poles and lines along the streets occupied by defendant were erected for such use. But this circumstance is immaterial, for it has been held, both in England and in this country, that the telephone system, which is communication over long and short distances through the agency of currents of electricity on metal wires, is really a magnetic telegraph system, and that an exclusive right to operate the telegraph includes the exclusive right to operate telephone lines.

Attorney-General *vs.* Edison Telephone Co., 6 Q. B. D. 244.

Wisconsin Tel. Co. *vs.* Oshkosh, 62 Wis. 32.

Nor does the passage of section 3471, which expressly makes the chapter on magnetic telegraph companies applicable to telephone companies, affect this conclusion. It was passed simply to remove the basis for an argument, and not because the chapter was not already sufficient to include telephone companies without it.

Chesapeake, etc. Tel. Co. *vs.* B. & O. Tel. Co., 66 Md. 399.

But, even if it were true that, when the plaintiff company, in 1878, began to use the telephone system, it was beyond its charter, it seems to me that the subsequent legislation of 1880 would have validated what before was *ultra vires*.

See Spring Grove Ave. Ry. Co. *vs.* Cumminsville, 14 Ohio St. 523.

I have not discussed, in this connection, the question how much the abutting property owners' rights were affected by the erection of the poles and wires of the plaintiff, because their rights are not in issue, and it is to be presumed, from the fact of plaintiff's occupation for so many years, in the absence of other evidence, that if any of the rights of the property owners were taken, they were ceded or sold to the plaintiff.

Having determined, then, that plaintiff's use of the streets, on which defendant operates its road, is lawful, the next question which arises is, whether defendant has the right to use electricity for the propulsion of its cars. If it has not, and it thereby interferes with plaintiff's franchise, it is very clear that such interference gives plaintiff a right of action. Defendant's counsel seems to contend that the question of *ultra vires* can not be raised against the defendant in this case; but that such an issue could only be made in an action by the state, or its delegated representatives, to oust the defendant from the exercise of such unwarranted privilege. This contention can not be sustained, for while it is true that if defendant is violating the limitations of its charter, plaintiff might request the attorney-general to institute *quo warranto* proceedings, nevertheless, it may rely on the fact of defendant's violation of its charter in a private litigation to show that the acts causing loss are unlawful.

City of Zanesville *vs.* Zanesville Gaslight Co., Supreme Court of Ohio, 23 W. L. B. 8.

The larger portion of the line now occupied by the defendant, was once operated by the Mt. Auburn Street Railroad Company, under a number of grants from the Common Council, the first of which was made September 2, 1864, and the last, November 14, 1873. All these grants were subject to the provisions of the general street railroad ordinance of 1859, that no motive power except horses and mules should be used on any road without the consent of Common Council. The franchise and property of the Mt. Auburn Railroad Co. was purchased by three persons: George A. Smith, J. M. Doherty, and Jos. S. Hill. On April 21, 1871, the Cincinnati Inclined Plane Railway Co. was incorporated under the general corporation act passed May 1, 1852, for the purpose of constructing a railroad whose termini should be in Cincinnati and the village of Avondale, and then constructed the inclined plane, still in use, connecting Locust street, Mt. Auburn, with the head of Main street. By ordinance, December, 1871, Common Council gave the company the power to lay tracks on certain streets which connected it with the Mt. Auburn street railroad tracks, with the express proviso that no motive power except horses and mules should be used on said tracks. A similar proviso was contained in an ordinance passed October 27, 1875, granting it the right to extend the tracks of the Mt. Auburn street railroad tracks to the north corporation line, at the Zoological Garden In 1876, an act was passed (73 Ohio L. 229), providing for the organization of inclined plane companies, and authorizing them to construct, operate, and maintain an inclined plane railroad for the conveyance of passengers and freight, or either, with such offices, depots, and other buildings as they may deem necessary; also, to establish and maintain a park or pleasure grounds, and for such purposes to hold real estate. Section 10 of this act, provided that whenever the part of the roadway of such railroad operated by steam power shall cross a public highway, such part of the railroad's railway shall pass either over or under such street or highway, and shall be constructed in such a manner and at such a distance above or below such street or highway, as not to obstruct the ordinary uses of such street or highway.

March 30, 1877, the legislature passed a law providing that any inclined plane railway company organized under the General Corporation Act of May, 1852, should have "the power to hold, lease, or purchase and maintain and operate such portion of any street railroad leading to or connected with the inclined plane as may be necessary for the convenient despatch of its business, upon the same terms and conditions on which it holds, maintains, and operates its inclined plane: provided, that no other motive power than animals shall be used on the public highways occupied by such street railway company without the consent of the Board of Public Works in any city having such a board, and the Common Council, or the public authority or company having charge, or owning any other highway in which such street railroad may be laid: and, provided, that no inclined plane railway or railroad company shall construct any track or tracks in any street or highway without first obtaining the written consent of a majority" of the abutting property holders.

June 19, 1877, George A. Smith, Jas. M. Doherty, and Jos. S. Hill leased the Mt. Auburn railroad perpetually to the Cincinnati Inclined Plane Railway Co. On September 24, 1885, the Board of Public Works passed a resolution consenting to the use by the defendant either of electricity, cable, or compressed air as a motive power "upon the highways in which the street railroads connected with its inclined plane, and held and operated by it are laid," on condition that defendant gave bond in $25,000 to hold the city harmless from any damages to persons or property arising out of the use of such motive power. On October 24, 1888, the Board of Public Affairs gave the defendant permission to erect along the entire length of its road the poles, wires, and appliances necessary to operate and maintain its entire line from Fifth and Walnut streets to the Zoological Garden as an electric road, in accordance with plans and specifications submitted to the board. The poles and wires were erected under the supervision of the engineer of the board. On February 23d, the stockholders of defendant extended its terminus to Glendale, Hamilton Co., Ohio, and certified the same to the Secretary of State under section 3306 of the General Railroad Chapter. And under such extension are now constructing a line of road along the Carthage pike under the consent of the County Commissioners, given March 23, '89, to use and occupy said pike with double tracks and with necessary appendages and appurtenances of an overhead electric street railroad system. This consent contains the provision that the County Commissioners are to cause the removal of any or all telegraph or telephone poles which may interfere with the operation of said electric road. The grant thus given was modified in September, 1889, but only with respect to the part of the street to be occupied.

Plaintiff's counsel maintain that on this record of the title of defendant, the present operation of this road is unlawful for several reasons.

First. That the act of 1876 providing for the incorporation of inclined plane railways requires that in passing over streets it should be conducted on bridges or in tunnels, and the act of May, 1877, provides that the operation of the railways to be leased shall be subject to the conditions upon which its inclined plane is operated.

Second. That the road connected with the inclined plane to be leased and operated by it under the act of 1877, was to be a "portion" of some other road, and that here the defendant is operating the entire road, nor is it shown that the road as used is necessary to the convenient despatch of the business of the inclined plane.

Third. That a proper construction of the first proviso of the act of 1877 requires that the consent necessary to permit the use of animal power shall be given by the Board of Public Works and the Common Council of the city.

As to the first reason, it should be said that it is doubtful whether the section referred to in the act of 1876 applies to defendant, for it does not appear that defendant ever accepted the provisions of that act as therein provided. Conceding, however, that the provision is of such a general character as to apply to any company running an inclined plane under whatever law organized, the restriction obviously applies only to places where the inclined plane itself crosses the streets, and not at all to what may be called surface street railroads which the Inclined Plane company is given power to lease and operate as street railroads are usually operated. The conditions upon which the inclined plane is operated, and to which the operation of street railways by the Inclined Plane company is to be subject, must, of course, be such conditions as are applicable to street railroads, of which the condition insisted on is obviously not one. Nor has the second reason, in my opinion, any weight. The original Mt. Auburn railroad company ran up Liberty, Price, Josephine, and Saunders streets. This portion of the road is not used now, but, being taken away, it leaves the part of Liberty to Fifth a portion, and that from Mason to the north corporation line a portion. As to the objection that such roads are not necessary to the despatch of the business of the inclined plane, I think it may be presumed that they are. It is common knowledge that the great difficulty to be overcome in reaching the plateaus about the city was in climbing the hills, and that the instrumentality by which that was accomplished became the principal feature of any such plan. The approach to the bottom and the departure from the top were incidental, and were certainly necessary to get passengers to the place of ascent or descent.

In so far as the third reason depends on the restriction in the grants to the Mt. Auburn railway to the use of horse and mule power, it is quite clear that subsequent legislative action enlarging the right of the lessee in this respect has been had, and no reason is apparent why it is not valid.

The chief argument is based on a construction of the proviso, "provided that no other motive power than animals shall be used on the public highways occupied by such street railway company without the consent of the Board of Public Works in any city having such a board, and the Common Council, or the public authority or company having charge, or owning any other highway in which such street railroad may be laid." Counsel for plaintiff argues that the body usually invested with the power of granting franchises for a municipal corporation, is the Common Council, and that it is not to be presumed that, in this case, the legislature intended to confer final power of that kind on the Board of Public Works, which is a body for the initiation of measures, not for their final legal sanction. Therefore, it is said, the word "and" before "Common Council" unites these two words with Board of Public Works, and the disjunctive "or" is the dividing word of the clauses, so that by a proper transposition it might be made to read "without the consent of the Common Council and of the Board of Public Works in any city having such a board, or of the public authority or company having charge, or owning, etc." This construction might be supported but for the use of the word "other" in the second clause. The clause is rather obscurely drawn, but the expression "any *other* highway in which such street railroad may be laid" means any highway additional to those already mentioned in which the same street railroad has been laid. The law is defining the consents required for one railroad passing through several jurisdictions. Therefore, we have the conjunctive *and* before Common Council to indicate that where a railroad has its beginning in the highways of a city having a Board of Public Works, and extends onto another highway beyond the city jurisdiction, it must have the consent of the Common Council or the public authority or company having charge, or owning such other highway in which such street railroad may be laid. The bill was evidently passed by the legislature with this city in their minds, for this is the only city in the state where an inclined plane would be necessary, and for this reason the peculiar phraseology is used. It would apply by virtue of the last clause after "*and*" to any other city, but as bearing on the effect of *and*, the probable and possible application of the law may be considered.

While it is true that to the Common Council is usually given the right to grant franchises, it is certainly within the legislative power to give it to the Board of Public Works or Affairs, and of late years there have been many instances where other powers, like those of passing ordinances to assess, and to make certain improvements, have been transferred from Council to the Board of Public Works. Moreover, if, by this law, the legislature intended to make the consent of the Board of Public Works and Council necessary, it was wholly superfluous to have mentioned the board at all, because, under section 2237 Rev. Stat., the Common Council could not grant such consent except upon the approval of the board. Some point is made of the presence of a comma after the words "Common Council" in the certified copy of the bill obtained from the Secretary of State's office, which does not appear in the printed law. I can not see that this materially affects the construction given above, for the certified copy shows the comma between board and the following *and* just as the printed law does, and that is the point where the question of a separation is important in construing the proviso.

On the whole, then, I am of opinion that the legislature conferred the right upon defendant to use any other motive power than animals, whenever the Board of Public Works should consent. Now, the board did consent, on October 24, 1885, that defendant should use either a cable, compressed air, or electricity. It has chosen electricity and has procured the necessary authority to erect its poles and string its wires.

Such being the condition of the franchises which the plaintiff and defendant are lawfully entitled to enjoy, considered each without reference to the other, it becomes necessary to inquire first whether any loss has been inflicted upon plaintiff by defendant, and if so, how it has occurred; second, whether such loss, if any, is justified by defendant's franchise, so as to be *damnum absque injuria*, which involves the preliminary question whether the legislature, after having given the plaintiff the right to construct its telephone system, on the faith of which right it has expended large amounts, can confer a franchise on another, the exercise of which will seriously impair the plaintiff's franchise as heretofore enjoyed.

First, a current of electricity can not be produced without a circuit, that is, unless the negative and positive poles of the generating battery or instrument are connected by a continuous substance, capable of conducting the current. Such a substance may be a metal wire, or if both poles of the battery be connected with the earth by metal wires, the current will find a circuit through the wires and the earth. The earth, by reason of its immense mass, makes an excellent conductor. By what paths the current discharged into it over the wire from one pole finds its way throughout to the wire from the other pole, is not capable of determination.

The telephone is a mechanism by which the sound of human speech is reproduced over long distances. Without attempting to describe the exact mode in which this result is brought about, I may say that the sound waves of the human voice produce vibrations in a thin ferrotype plate, which, by means of a magnet and an induction coil, are converted into corresponding variations in an electric current on the connecting wire, and these variations are, in turn, by means of the inducing coil and magnet at the other end, converted into exactly corresponding vibrations on a plate there, reproducing the sound waves of the voice of the speaker in such a manner as to enable the receiver to understand. The current on the connecting wire is a slight one, and the circuit is completed, not by a return wire, but by a ground wire brought into contact with the earth. This contact is usually made by attaching the wire from the negative pole of the single cell battery in each telephone, to a gas pipe or water pipe running down into the earth.

In the Sprague system of electric railways, which is the kind used by the defendant, the electricity used to operate the motors under the cars is conveyed to them by a single overhead wire suspended over the middle of the track, along the underside of which runs a trolley wheel on a single mast attached to the car, making electric connection between the overhead wire and the motor of the car, and allowing the current to pass down through the motor, and onto the track, whence some of it returns directly to the dynamo generator at the power house. A large part of the electricity leaves the track, however, and, by other and various paths, also finds its way through the earth back to the dynamo. In addition to the overhead trolley wire, which is supported by guide wires from iron posts erected on the curb at regular intervals, there is what is called a feed wire strung along on these posts for the purpose of keeping up the required quantity of electricity on the trolley wires. On the streets where are telephone wires, and electric railway wires, their general course must be parallel. The evidence in the case establishes beyond a doubt, that, since the defendant began the operation of its line by electricity, in June, 1889, down to the time of trial, the usefulness of all the telephones along the line of the railway have been more or less impaired; that, in many cases, the buzzing noise, which seems to be the chief form of the disturbance, has been so loud and continuous that communication over the lines has been impossible. Nor has the disturbance been confined to telephones on the line of the railway. Telephones several miles from the city, whose connecting wires ran parallel for any distance with the railway, were similarly affected, and the buzzing noise, in many of these, seems to have been quite as deafening as in telephones along the line. Altogether, more than two hundred lines have been affected in this way, to a greater or less degree. The cause of the trouble is undoubtedly the operation of the electric railways, and the way by which it is brought about is two-fold. First, the escape of the electric fluid from the rails, which is called earth distribution or leakage, near where the wire from the telephone is connected with the earth, brings upon this earth connection wire of the telephone varying currents of electricity of much greater quantity than that necessary for the telephone current, and produces upon the magnet and inducing coil an affect which results in vibrations of a very different character from those produced by the human voice, and makes a noise like the buzzing of a saw. Second, a similar noise is made by induction. It is a physical fact of much importance in electric mechanism that, where two wires of two circuits are parallel to each other, and there is a current of varying intensity on one of them, this will produce in the other, in the opposite direction, a current of electricity of similar variation. The insulation of the wires has no effect to reduce the current produced in this way. The amount of induction depends upon variation in the current, the distance of the wires from each other, and the length of the parallelism of the wires. The current upon the trolley wire, and the feed wire of the railway is quite variable in quantity and intensity, owing to the drain upon the store of electricity by the moving and stopping of the car. Nor is the electricity, as generated, exactly uniform in its flow from the dynamo. The result is that, wherever the telephone wire is parallel with the trolley wire and the feed wire, there is induced upon the telephone wire a current whose variations correspond with the variations of the electrical current on the electric railway wires, and this, acting upon the inducing coil and magnet, produces vibrations of the tin plate, which makes the buzzing sound. It is not possible, in listening to the sounds produced by the electric railway, to say whether it is the result of induction or earth leakage. Some of plaintiff's subscribers, notably Proctor & Gamble, have loud buzzing sounds upon their telephones, the ground wires of which are at such a distance from the railway track as to make it quite unlikely that the disturbance could have been caused by earth leakage, while, on the other hand, their wires are for some distance parallel with the trolley and feed wire of the railway company. Other telephones are disturbed on the line of the road, though their wires are not parallel with the trolley wire. Expert evidence attributed the disturbance about one-half to induction, and one-half to conduction or earth leakage. This, of course, is only a rough estimate, and the fact may vary much in particular instances. The injury to plaintiff's service is produced then, speaking in a general way, one-half by the defendant pouring electricity into the earth, which finds its way into the property of plaintiff's subscribers, and thence into the wire of the telephone, and one-half by a creation of a current on plaintiff's wires in the street by the parallelism of defendant's wire and the varying character of the current. The result has been a very substantial interference with the plaintiff's business, and, if the present condition continues, it will end in a serious loss.

Is it a loss for which defendant is liable? The contention on behalf of the defendant is, that because it has full power to operate by electricity under the law, the loss resulting to the plaintiff is *damnum absque injuria,* and if the plaintiff wishes to avoid the loss, it must adopt safeguards in the shape of a metallic circuit to avoid the difficulty. To this plaintiff replies, that, by virtue of its grants, it acquired, before the defendant had a right to use electricity as a motive power, a vested interest in the telephone system as it now operates it, with a grounded circuit, and that not even the legislature of the state could take away from it or injure this franchise, on the faith of which it has expended so much capital and labor.

I am inclined to think that, under the constitutional provision that all laws for the forming of corporations may be altered or repealed (sec. 2, art. xiii), it would be in the power of the legislature to grant a right to other corporations for a public use to so use the street as to require the plaintiff company, if it wished to continue in the telephone business, to change its system, and that without any right of action against such corporations. The case of Ry. Co. *vs.* Ry. Co., 30 Ohio St. 604, shows that, where one railway company condemned a right of way across the track of another, that other cannot recover for an injury to its franchise as a railroad or for the increased expense entailed upon it in obeying laws of the state with reference to railroad crossings. However this may be, I am very clear that no intention on the part of the legislature to abridge the granted rights of one corporation by a new grant to another will be recognized by the courts unless such intention plainly appears in the law. In England, the power of Parliament is unlimited, and it may even confiscate private property, and *a fortori* may abridge and destroy chartered rights and franchises. Nevertheless, we find in that country, that where one corporation is granted a right which may be so exercised as to injure or interfere with a right previously granted to another, the presumption of law is that Parliament intended only such uses as was consistent with the rights of the first corporation. In Gas Light and Coke Co. *vs.* Vestry, 15 Q. B. D. 1, plaintiff was a gas company, which had laid its gas pipes by virtue of a public grant under a street which the defendant, a public corporation, was charged with keeping in repair, and upon which it used such heavy rollers as to injure the pipes of the plaintiff. The rolls used were economical and well fitted for the purpose, but it was held that, unless the defendants were expressly authorized by statute to use rollers of the size and weight of those which did the injury, the defendant could not justify under a duty to keep in repair which might be discharged by rollers of less weight and without breaking the pipes. Says Findley, L. J.: "The authorities * * * show that an action lies for injury to property, unless such injury is expressly authorized by statute, or is, physically speaking, the necessary consequence of what is authorized. If in this case the defendants were expressly authorized by statute to use steam rollers of such a weight as necessarily to injure the plaintiffs' pipes, the plaintiffs would have no ground of complaint. The case would then be one of *damnum absque injuria.* The same consequence would follow if the defendants were expressly authorized by statute to repair in some way which necessarily required the use of heavy steam rollers or other machinery, which could not be worked without injuring the plaintiffs' pipes. There again, although such rollers or machinery were not expressly mentioned, their use would be authorized by necessary implication, and the plaintiffs would be without redress. But unless some statutory enactment can be shown to authorize the defendants to injure the plaintiffs' pipes the plaintiffs are entitled to redress." This case is peculiarly applicable to the case at bar, because here was a case of a public grant to the gas company enjoyed in a certain way, followed by a grant to the defendant to exercise another right, which if exercised in one way would injure plaintiff's enjoyment of its right, and which if exercised in another would not. The same principle is here applied that courts recognize wherever private property is injured by the exercise of authority granted by the Parliament.

See

Hammersmith, etc., Ry. Co. *vs.* Brand, L. R. 4 H. L. 171.
Queen *vs.* Bradford Navigation Co., 6 B. & S. 631.
Geddis *vs.* Proprietors of Bann Reservoir, 3 App. Cases 430.
Att'y Gen'l *vs.* Colney Hatch Lunatic Asylum, L. R. 4 Ch. App. 416.
Att'y Gen'l *vs.* Gas Light & Coke Co., 7 Ch. D. 217.
Managers Metrop. Asylum District *vs.* Hill, 6 App. Cases 193.

Even then, if franchises to occupy the public streets conferred by the legislature may be subject to modifications of their use and enjoyment by other public grants of the legislature, it is certain that unless the legislative intent to make such modification clearly appears, either by express words or by necessary implication arising from the impossibility of enjoying the second grant without such modification, it will not be inferred.

But it is said that this principal can have no place here because the right to occupy the street for the purpose of travel is a superior right to that of using it for the telephone poles. Defendant's counsel, to establish this, rely on

The Spring Grove Ave. *vs.* Cumminsville, 14 Ohio St.,
Smith *vs.* Tel. Co., 2 C. C. R. 259.
Mt. Adams & E. P. R. Co. *vs.* Winslow, 3 C. C. R. 425.
R. R. Co. *vs.* Williams, 35 Ohio St. 171.
Pike's Ex'rs *vs.* Western U. Tel. Co., decided by this court.

These cases have no bearing upon this case at all, as it seems to me. They involved a discussion of whether the erection of certain structures in the street could be considered a new burden and use, not included in the easement, which the abutting property holder had originally granted to the public, and whether, therefore, he was entitled to compensation. It is unquestionably within the power of the legislature, so far as the public is concerned, to enlarge the benefit to be derived from the streets, so as to include other public purposes than those of mere travel. Ry. Co. *vs* Lawrence, 38 Ohio St. 45. If this takes more from the abutting property holder than he originally gave, then he may have compensation, but the public can not complain, for their representative, the legislature, has spoken and granted the use. When the telephone company is granted the right to use the streets, its right is as well founded as that of a street railway company, and in the absence of express legislative direction to the contrary, there is to be no yielding to any other. The provision that the telephone and telegraph lines shall not incommode the public in the use of the street, in section 3461, does not help the defendant. The inconvenience must be determined when the enjoyment of the franchise is entered upon. After going is a true and correct copy of an order made by the said court on the 12th day of February, 1890, Min. 564.

Witness my hand and the seal of said court, at Cincinnati, this 14th day of February, A. D. 1890.

[SEAL.] JOHN B. PEASLEE, *Clerk*.
By R. H. BECHT, *Deputy*.

MISCELLANEOUS.

In the suit of the Wisconsin Telephone Co. *vs.* the Sprague Electric Street Railway Co., operating at Eau Claire, Wisconsin, for an injunction, Judge Bundy, on January 29th, refused to grant the application of the plaintiff.

At Torrington, Ct., the suit of the Southern New England Telephone Co. against the Torrington Electric Light Co., has been withdrawn, an amicable settlement having been made. The electric light company recently signed a telephone contract, made all its circuits metallic and parallel, and the plaintiff withdrew the suit and paid the costs.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From January 14 to February 11, 1890 (inclusive).

Alarms and Signals:—*Draft Annunciator for Mines*, W. Bullock, 419,312, January 14. *Automatic Fire Alarm*, E. Wider, 419,902. *Alarm*, J. Catz, 419,924, January 21. *Electric Fire Alarm System*, J. Speicher, 420,173. *Ocean Signal*, W. Thompson and A. Gartner, 420,217. *Electric Signal*, J. D. Taylor, 420,256, January 28. *Burglar Alarm*, N. M. Powell, 420,697. *Electrical Recording Instrument*, F. B. Wood, 420,850. *Method of Electrically Recording Signals*, same, 420,851. *Apparatus for Electrically Recording Signals*, same, 420,852. *Electric Time Alarm and Indicator*, C. A. Randall, 420,890, February 4. *Electric Compound Push*, J. F. Wollensak, 421,340, February 11.

Clocks:—*Electrical Clock*, A. R. Jones, 419,776, January 21.

Conductors, Conduits and Insulators:—*Insulator for Electric Wires*, I. P. Cornog, 419,642. *Screw Press for Insulators*, J. Pease, 419,875. *Electrical Conductor*, H. H. Carpenter, 419,923. *Insulating Pipe Joint*, G. M. Lane, 419,962, January 21. *Insulating Casing*, J. A. Seely, 420,171. *Gas-Pipe Insulating Device*, E. W. Rice, Jr., 420,391, January 28. *Staple for Electrical Conductors*, L. Stieringer, 420,635. *Insulating Compound*, J. B. Williams, 420,648. *Machine for Covering Wire, &c.*, F. E. Davis, 420,777, February 4. *Conduit for Electric Cables*, W. P. Tyler, 421,088, February 11.

Distribution:—*Electric Transformer*, E. Thomson, 420,396, January 28. *System of Generators*, A. G. Waterhouse, 420,924, February 4. *Transmission of Power by Electricity*, E. W. Rice, Jr., 421,193. *System of Distribution for Alternating Currents*, E. Thomson, 421,208, February 11.

Dynamos and Motors:—*Electric Motor*, S. C. C. Currie, 419,245, January 14. *Electric Commutator*, L. Gutmann, 419,660. *Dynamo and Motor*, same, 419,661. *Electric Commutator*, same, 419,662. *Method of Producing Alternating Electric Currents*, same, 419,663. *Alternate Current Motor Regulator*, same, 419,664. *Thermo-Dynamic Motor*, C. W. Weiss, 419,805. *Electric Motor*, Le R. S. White, 419,808, January 21. *Electric Motor and Regulator therefor*, E. A. Sperry, 420.117. *Regulator for Dynamos*, J. J. Wood, 420,138. *Governor for Dynamos or Motors*, A. G. Waterhouse, 420,338, January 28. *Regulation of Electric Motors*, L. W. Serrell, 420,469. February 4. *Regulator for Dynamos*, E. Heymann and F. W. Heymann, 421,048. *Starting Switch for Electric Motors*, W. A. Anthony, 421,090. *Motor for Electric Regulating Apparatus*, F. Ross and A. Franzen, 421,195. *Commutator for Dynamos, Motors*, etc., G. H. Alton and W. O. Wakefield, 421,222. *Collecting Contact for Electric Machines*, A. Schmid and E. C. Means, 421,320, February 11.

Galvanic Batteries:—*Galvanic Battery*, W. Burnley, 419,633; L. T. Stanley, 419,730; W. E. Irish, 419,774, January 21. J. F. Mehren, 421,081. *Electric Battery*, E. M. G. Hewett, 421,169, February 11.

Lamps and Appurtenances:—*Hood for Electric Lamps*, D. A. Culman, Jr., 419,186. *Shade for Incandescent Electric Lights*, J. H. Huber, 419,524. *Socket for Incandescent Lamps*, C. H. Lawton, 419,617, January 14. *Electric Lamp*, S. B. Cobb, 419,829, January 21. *Incandescent Lamp Socket*, H. Lemp, 420,077. *Electric Arc Lamp*, C. E. Scribner, 420,109; R. Schefbauer, 420,314. *Incandescent Lamp-Socket*, M. J. Wightman, 420,370, January 28. *Electric Lamp Adapter*, J. Stewart, 420,704 and 420,706. *Filament for Incandescent Lights*, R. Langhans, 420,881, February 4. *Cut-out for Incandescent Lamps*, E. Thomson, 421,207, February 11.

Measurement:—*Method of Making Electrolytic Meters*, A. E. Kennelly, 419,264. *Meter for Alternating Electric Currents*, O. B. Shallenberger, 419,367, January 14. *Electric Meter*, W. F. Smith, 420,214, January 28. J. D. Bishop, 420,762, February 4.

Medical and Surgical:—*Portable Faradic Battery*, L. T. Stanley, 419,731, January 21. *Therapeutic Magnet*, T. H. Hicks, 420,300, January 28. *Electric Belt*, A. J. Sheffield, 420,740. *Electro-Magnetic Abdominal Support*, M. E. Thomas, 420,840, February 4.

Metal Working:—*Electric Soldering Iron*, W. M. Miner, 421,185, Feb. 11.

Miscellaneous:—*Electric Steam Generator*, J. O'Meara, 419,282. *Electric Connector*, J. A. Seely, 419,365. *Electric Cut-out*, J. F. Wollensak, 419,487 January 14. *Shield or Protector for Electric Conductors of Combined Gas and Electric Fixtures*, J. C. Hollings, 419,674. *Electric Protective System*, A. C. Robbins, 419,710. *Cut-out*, C. B. Story, 419,733. *Electro-Thermal Current Regulator*, F. C. Wagner, 419,740. *Electric Door Opener*, A. Glaeser, 419,766. *Electric Reciprocating Tool*, H. N. Marvin, 419,861, January 21. *Wind-Vane Indicator*, H. J. Haight, 420,057. *Electric Detecting Apparatus for Coin-Actuated Boxes*, W. J. Howey, 420,070. *Electric Reciprocating Tool*, H. N. Marvin, 420,079 and 420,080. *Lightning Arrester*, C. A. Pfluger, 420,096. *Automatic Safety Cut-off for Electric Circuits*, G. M. Guerrant, 420,198. *Magnetic Separator*, G. Conkling, 420,334. *Advertising Automaton for Store Windows*, G. Music, 420.351. *Current Direction Indicator*, E. P. Warner, 420,422, January 28. *Thermal Cut-out*, G. Farrell, 420,444. *Electric Drill*, I. E. Story, 420,500. *Extension Electrolier*, J. E. Brown and J. F. Brown, 420,552. *Automatic Bolt Work*, O. E. Pillard, 420,563. *Electric Brush*, J. E. Stephens, 420,611. *Electrical Lock-Switch*, E. N. Dickerson, 420,622. *Method of Electric Refrigeration*, M. W. Dewey, 420,641. *Bipolar Prostatic Electrolyzer*, R. M. Bache, 420,710. *Thermo-Electric Generator*, C. S. Bradley, 420,764. *Electrically Reciprocating Tool*, H. N. Marvin, 420,816. *Electric Door Opener*, G. A. Seib, 420,834. *Electric Regulating Mechanism*, H. Lemp and M. J. Wightman, 420,882. *Rheostat*, W. Thomson, 420,894, February 4. *Electric Body Battery*, O. S. Hall, 420,936. *Electro-Mechanical Movement*, S. E. Nutting, 420,954 and 420,955. *Electric Vote Indicator and Recorder for Legislative Bodies*, W. H. Robinson, 420,964. *Lightning Arrester*, G. G. Bayne, 420,984. *Thermo-Electric Resistance-Regulator*, S. E. Nutting, 421,053. *Art of Making Cores for Electro-Magnets*, S. C. C. Currie, 421,067. *Switch-Board*, W. M. Stewart, 421,114. *Safety Device for Electric Circuits*, H. Lemp, 421,177. *Cut-out*, E. W. Little, 421,179. *Thermal Cut-out*. same, 421,180. *P. Cardew*, 421,240. *Electrical Spray and Vapor Bath*, N. Lyke, 421,294. *Door-Alarm*, J. F. Wollensak, 421,339, February 11.

Railways and Appliances: -*Conduit for Electric Railways*, B. J. Black, 419,308. *Electric Street Railway*, B. J. Black and W. F. Jenkins, 419.309. *Electric Railroad Telegraph*, B. Cade, 419, 313. *Electric Railroad*, same, 419.314. *Electric Railway*, I. Kitsee, 419,588, January 14. *Electric Railway System*, T. E. Adams, 419.618. *Electrical Railway System*, T. H. Hicks, 419,673. *Electric Railway System*, C. Ritchter, 419,709. *Electric Locomotive*, W. H. Darling, 419,753. *Overhead Contact and Switch*, R. W. Hawkesworth, 419,771. *Electric Railway*, M. W. Dewey, 419,841, January 21. *Conduit for Electric Street Railways*, J. W. Reno, 420,101, January 28. *Electric Street Car Gear*, E. Peckham, 420,543. *Electric Car Gear*, same, 420,544. *Electric Car Axle*, same, 420,545. *Electro-Magnetic Car Brake*, D. S. McElroy, 420,693. *Conduit for Electric Railways*, D. E. Johnson, 420,804. *Electric Railway Signal*, G. W. Boss, 420,858 and 420,859, February 4. *Railway Electric Signal*, P. D. Cable, 421,239. *Trolley for Electric Railways*, F. B. Rae, 421,304. *Overhead Trolley for Electric Railways*, same, 421,305, February 11.

Secondary Batteries:—*Method of Treating Secondary Battery Plates*, C. Sorley, 419,727. *Electrode for Secondary Batteries*, same, 419,728. *Secondary Battery*, J. F. Mehren, 419,862, January 21. *Plate for Secondary Batteries*, G. A. Johnson, 420,284, January 28. *Apparatus for Charging and Discharging Secondary Batteries*, W. S. Johnson, 420,906. February 4. *Storage Battery*, C. Sorley, 420,975, February 11.

Telegraphs:—*Telegraphic Transmission of Index Movements*, F. Richard, 420,102. *Printing Telegraph*, J. F. McLaughlin, 420,240. *Printing Instrument or Apparatus for Telegraphic or Other Uses*, J. H. Rogers, 420,358. *Electrical Communicating System*, A. G. Holcombe, 420,384. *Telegraph Apparatus*, E. B. Shafer, 420,393, January 28. *Quadruplex Telegraph*, T. A. Edison, 420,594. *Autographic Telegraph*, J. H. Robertson, 420,833. *Multiple Telegraphy*, E. J. P. Mercadier, 420,884, February 4. *Telegraphic Sounder*, G. W. White, 421,214. *Electrical Communication*, J. L. Cutler, 421,371, February 11.

Telephones and Apparatus:—*Telephone Circuit and Apparatus*, J. N. Culbertson, 419,645. *Mechanical Telephone*, R. C. M. Bowles, 419,986, January 21. *Testing Apparatus for Telephone Exchange Switches*, J. J. O'Connell, 420,091. *Telephone Exchange Apparatus*, F. G. Beach and F. B. Cook, 420,183, January 28. *Telephone Transmitter and Receiver*, H. W. Libbey, 421,006. *Attachment for Telephones*, G. F. Newland, 421,011, February 11.

EXPIRING PATENTS.

Patents relating to Electricity which become Public Property in March, 1890.

Reported for the ELECTRICAL ENGINEER, by F. B. Brock, *Patent Attorney*, 639 *F street, Washington, D. C.*

Multiple Telegraph, M. Galle, 136,369, March 4, 1873. *Duplex Telegraph*, J. C. Wilson, 136,400, March 4, 1873. *Annunciator*. Shawk & Storer, 136,465, March 4, 1873. *Annunciator*, W. Humans, 136,518, March 4, 1873. *Electrolysis Apparatus*, I. Adair, Jr., 136,634, March 11, 1873. *Duplex Telegraph*, J. B. Stearns, 136,873, March 18, 1873. *Duplex Telegraph*, J. B. Stearns, 136,874, March 18, 1873. *Telegraph Key*, J. B. Stearns, 136,875, March 18, 1873. *Relay and Sounds*, J. B. Stearns, 136,876, March 18, 1873. *Electric Gas Lighting*, L. B. Moody, 136,930, March 18, 1873. *Printing Telegraph*, C. J. Wiley, 137,117, March 25, 1873.

[Drawings and specifications of any patent will be furnished by Mr. Brock at cost, 15 cents each.]

THE
ELECTRICAL ENGINEER.
[INCORPORATED.]
PUBLISHED EVERY WEDNESDAY AT
150 Broadway, New York City.

GEO. M. PHELPS, President. F. R. COLVIN, Treas. and Business Manager.

Edited by
T. COMMERFORD MARTIN AND JOSEPH WETZLER.

New England Editor and Manager, A. C. SHAW, Boston, Mass.
Western Manager, W. F. COLLINS, Chicago, Ill.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. IX. NEW YORK, APRIL 2, 1890. No. 100

All the elements whose aid man calls in will sometime become his masters, especially those of most subtle force. Shall he, then, renounce steam, fire and electricity, or shall he learn to deal with them?—Emerson.

A PARTING WORD.

MORE than five years ago, at the earnest solicitation of many friends interested in the advancement of electrical science, the undersigned, not without considerable reluctance, consented to assume the editorial management of this journal. An opinion was entertained, which has been amply justified by results, that there existed in this country an almost wholly unoccupied field for a publication which should aim to devote itself more especially to the scientific and professional than to the distinctively commercial aspects of the electrical industries; which should constitute a vehicle for the publication and discussion of important professional papers, and which should present from month to month a well-digested record of the progress of theoretical and applied science in this department throughout the world. It must be left for others to judge what measure of success may have at first attended the undertaking, but it has for some time been apparent that by reason of the unparalleled and unforeseen expansion of the field of electrical work all over the world, the programme originally laid out could not possibly be fulfilled, to the acceptance either of the patrons or of the management of THE ELECTRICAL ENGINEER, unless arrangements could be made to issue it more frequently, a step which was felt to have become imperative, and which would have been taken long ago but for the added burden of labor which circumstances rendered it impossible for its conductors to assume. In retiring from the editorial chair, the undersigned desires to express his sincere thanks to the appreciative contributors, advertisers and readers, who have so effectively aided him in his efforts to carry out his design. He would also add, that he esteems himself peculiarly fortunate in having been able to place THE ELECTRICAL ENGINEER in the hands of editors so widely and so favorably known to the profession throughout the world as are Messrs. Martin and Wetzler. FRANKLIN LEONARD POPE.

GREETING.

WITH its 100th number THE ELECTRICAL ENGINEER celebrates its century of months by appearing for the first time as a weekly journal. It will henceforth issue and be dated Wednesday of each week. The new organization of the editorial and of the business staff under which THE ELECTRICAL ENGINEER will be conducted is fully set forth elsewhere in this issue. The preliminary announcements of the enlarged plans of this journal have met with such general and cordial approval on all sides as to confirm beyond question the judgment of the proprietors in undertaking them.

The present issue further distinguishes its serial number by containing, with happy coincidence, exactly 100 pages. Following the last previous issue by a month, the accumulation of matter has rendered necessary a somewhat larger amount of reading in this than our subscribers and friends might naturally expect every week—for the present.

In assuming the office of president of the corporation organized as THE ELECTRICAL ENGINEER, the subscriber desires to join with Mr. Pope in expressing his sense of gratification in seeing the editorial chairs occupied by Mr. Martin and Mr. Wetzler. GEORGE M. PHELPS.

A LEGAL MONSTROSITY.

WE have never felt any hesitation in saying, as we have done on more than one occasion, that the provision in the Federal Statutes by which the duration of a prior foreign patent is permitted in any way to affect the validity or life of a domestic patent, was a relic of barbarism which ought to be summarily swept away. In THE ELECTRICAL ENGINEER of March, 1889, we expressed the opinion that under the doctrine announced by the Supreme Court in the Bate decision, the forfeiture of foreign patents for non-payment of taxes would be likely to affect adversely a subsequently issued domestic patent, a view in which we were afterwards supported by Justice Thayer, in his opinion in *Huber* v. *Nelson Mfg. Co.*, two months afterward. In the May number of THE ELECTRICAL ENGINEER, commenting further upon this matter we said :—

> We are forced to admit that it would not be an unprecedented circumstance, if the next time the question comes up, the Supreme Court should decide it exactly contrary to the logical deduction which necessarily follows from the text of its opinion in the Bate case.

This is exactly what the Supreme Court has now done, as will appear from its decision just rendered in *Pohl* v. *Anchor Brewing Co.;* the main points of which are given elsewhere in this issue. Section 4,887, has in fact been knocked back and forth across the arena so many times that it has become, so to speak, dilapidated and frayed out at the edges. The variety, no less than the inconsistency, of the several interpretations which have been put upon it by learned jurists would afford a subject of curious interest merely, but for the dependence of vast commercial interests upon the final result—if there ever should be a result which could be so considered. Not the least singular fact in connection with these contradictory decisions, is that the more important of them have been written by one and the same justice. A comparison of three of these decisions is calculated to throw a shade of doubt upon the assertion of Blackstone that "the law is the perfection of human wisdom."

Justice BLATCHFORD.	Justice BLATCHFORD.	Justice BLATCHFORD.
It is also contended by the plaintiff that the Austrian patent, though granted for the duration of one year on its face, was really a patent for 15 years. It might have been prolonged year by year, or otherwise, for five years beyond December 30, 1880. But it was not prolonged beyond that date, and at most it cannot be regarded as a patent which, when granted, had a longer term to run than till December 30, 1880. even if it could be considered as a patent having when granted a longer term to run than one year. *A capacity of being prolonged so as to have a duration of* 15 *years is not equivalent to having a term of* 15 *years, when the patent is granted for one year and then is prolonged so as to expire at the end of* 10 *years.* * * The Austrian patent conferred on the patentees an exclusive privilege. *It was the manifest intention of Section* 25, *of the Act of* 1870, *that the exclusive privilege under the patent here should expire with the exclusive privilege granted abroad to the same inventor having the shortest term.* As the Austrian patent expired at the latest, on December 30, 1880, and before this suit was brought, and No. 120,057 *continued to exist no longer*, there was no ground for this suit in equity when it was brought.	Section 4,887, of the Revised Statutes, provides that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent, or, if there be more than one, at the same time with the one having the shortest term, and in no case shall it be in force more than 17 years." *These provisions of the Act of* 1870, and of the Revised Statutes, *mean that the United States patent shall not expire so long as the foreign patent continues to exist*. not extending beyond 17 years from the date of the United States patent, *but shall continue in force*, though not longer than 17 years from its date, *so long as the foreign patent continues to exist.* Under Section 4,887, although, in the case provided for by it, the United States patent may on its face run for 17 years from its date, *it is to be so limited by the courts, as a matter to be adjudicated on evidence in pais, as to expire at the same time with the foreign patent*, not running in any case more than the 17 years; but, subject to the latter limitation, *it is to be in force as long as the foreign patent is in force.*	*There is nothing in the statute which admits of the view that the duration of the United States patent is to be limited by anything but the duration of the legal term of the foreign patent in force at the time of the issuing of the United States patent, or that it is to be limited by any lapsing or forfeiture of any portion of the term of such foreign patent, by means of the operation of a condition subsequent, according to the foreign statute.* In saying that "every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent," the statute manifestly assumes that the patent previously granted in a foreign country is one granted for a definite term; and its meaning is, that the United States patent shall be so limited as to expire at the same time with such term of the foreign patent.

In view of this record, we respectfully submit, that instead of making any further efforts to discover the intentions of the maladroit who inserted this provision in the patent law, the Supreme Court be relieved from further consideration of it, by its immediate repeal.

EFFICIENCY OF ALTERNATING APPARATUS.

EVER since the alternating current apparatus entered the field of electric distribution, a brisk controversy has been carried on as to the efficiency of that class of apparatus as compared with the continuous. Though much acute reasoning was brought to bear on the subject, there has up to the present been little reliable data of an independent source available for a practical comparison, and that in existence related merely to individual devices in connection with the alternating system. Thanks to the labors of Dr. Duncan and Mr. W. F. C. Hasson, however, we are now placed in possession of data which is undoubtedly reliable, and which, while giving the tests of all the individual apparatus of the alternating system, includes the efficiency of the system as a whole from the dynamo pulley to the lamp. The analysis of the results would seem to show that the principal loss encountered is to be detected in the armature of the dynamo, and this fact, we believe, is now well recognized by the manufacturers of alternate current apparatus, so that improvement of the kind needed may be looked for at no distant date, embodying among other changes the application of the toothed armature instead of the plain cylindrical as heretofore employed. The converters are shown to be quite efficient, and the curious relation is brought out that the loss in their cores is nearly constant for all loads. It is this constancy of relation that, as Mr. Tesla pointed out in the discussion before the American Institute of Electrical Engineers, may ultimately establish the correctness of the hypothesis advanced, that in reality there is practically no loss due to hysteresis, and that the changes of magnetization represent a charging and discharging of molecular energy without entailing an actual expenditure of energy. The losses, then, must be due to eddy currents principally, and the remedy is obvious. Dr. Duncan, in the discussion, also gave expression to his views on the application of the system of distribution, alternating and continuous, which we think are now being generally adopted by intelligent electrical engineers. According to these, the circumstances of each case must dictate which is the more economical to apply, and hence no hard and fast rule can be given. Where the density of population permits of it, the low-tension system of distribution is apparently the more economical; but where the consumers are scattered, as they are in a vast number of towns and cities, and at such distances from the station that direct working would involve too great a loss, the converter system is eminently applicable. Dr. Duncan goes further and gives it as his opinion that the best results could be obtained by a combination of both systems in a central station which would thus be able to accept all the business offered to it independent of distance. That these views are sound is evidenced by the fact that they have already been put into practical operation in a few instances by men of leading, and we cannot but believe that in this direction will be found the settlement of a long-waged and earth-shaking controversy in the industrial domain of electricity.

STORAGE BATTERY LITIGATION.

THE decisions in the various suits bearing on the validity and ownership of important inventions in electricity are now following one another in such rapid succession that the time cannot be far distant when the exact status of various important and fundamental inventions will be finally established. This is notably so in the case of the storage battery. Following close upon Judge Coxe's decision awarding to Faure the patent for the application of the active material to a storage battery plate in the form of paint, paste or cement, comes another by the same judge, in which the broad principle of the application of active material to such a plate is awarded to Mr. Brush. The decision, though of considerable length, will nevertheless bear perusal as it disposes of a number of points which are of general and even vital interest to inventors. Thus Judge Coxe regards "absorptive" and "active" material as applied to a storage battery as synonymous terms, and holds the two patents covering each individually to be equivalents of each other; and hence the anomalous condition is brought about that two patents have been issued for the same thing. In the present instance, no particular harm has been done, but Judge Coxe raises the question as to the harm that might have been done had one of these patents been assigned to another party. The expired Italian patent of Brush was brought into evidence to show the invalidity of the United States patent, but on this point Judge Coxe gave the benefit of the doubt as to the identity of the two to Brush, and held the Italian patent not to cover the same points as the one in litigation. Even if Judge Coxe had decided otherwise, the recent decision of the Supreme Court, commented on elsewhere, would have sustained Brush in his rights, so that this point may be considered as definitely settled. With the decision in Mr. Brush's favor, and in the absence of an appeal, it gives him practically the control of the storage battery in this country, and as a working arrangement between him and the Julien company has, it is understood, been effected, some important developments may be expected in the near future.

Alternating Arc Lights.

We present to our readers in this issue a complete description of the new Westinghouse arc light system, which has been the subject of much curiosity and not a little comment in electrical circles. In this system the Westinghouse company is evidently carrying out to its logical conclusion the opinions held by it in regard to the alternating incandescent system, according to which the consumers' apparatus, the lamp and accessories, are entirely dis-disconnected from the high tension circuit. The self-regulating qualities of the machine due to the peculiar construction of the armature and winding are of particular interest and show the remarkable flexibility as well as applicability of the alternating current to particular cases. The record of power tests of one of the large machines of this type will also arrest the attention of station managers. As will readily be observed, the details of the system have been carefully worked out, and the results are such as to justify the expectation that it will be widely introduced.

Predictions of a "Trust."

Rumors are current in electrical circles, and even in the daily press, of measures on foot among leading electrical manufacturing companies preparatory to further amalgamation of interests, and the consequent elimination from the situation of a great part of the prevailing competition for business as well as of much patent litigation. Predictions are indulged of the eventual formation of a great electrical trust to absorb all the prominent electric light and power interests. Further consolidations may reasonably be looked for in the near future, but it seems to us very unlikely that a comprehensive electrical trust will be seriously undertaken by even the most daring of the able administrators now controlling the affairs of the few very large companies. The complexity of the conditions to be dealt with in organizing and maintaining an electric light and power trust is very great, incomparably greater than in the case of such industries as the manufacture of oil, sugar, white lead and the like. No combination of patents would sustain a general monopoly for any certain period. The common ground now open to electrical manufacturers, so far as regards patent control, is spacious enough to entice capital into new enterprises, many of which are constantly springing up in all directions. Moreover, the possibility of new and radical discovery or invention in the production or distribution of electricity adds an incalculable element to the situation far greater than obtains in other industries. With or without patent control, combinations or trusts, it is safe to say that nothing can be surely relied upon for permanent success in the field of electrical business, whether by one organization or by many, without a ruling policy of sound engineering, stable construction in all details, careful economy and moderate profits. The present competition among the principal companies brings about such a policy for the most part, and has perhaps moderated the profits too greatly for the satisfaction of share holders.

In Season and Out.

Tempted by the early mildness of the spring, an enterprising electric motor agent in a city not many miles from New York prepared a batch of tasteful fan outfits a few weeks ago, and began to distribute them in a number of stores, restaurants, etc., where their cooling zephyrs would be best appreciated. The very day he sent them out the weather changed, and the men entrusted with the work put up the motors with numbed fingers, while there raged outdoors the heaviest snow storm of the year. Such an incongruity of situation might well have dampened the ardor of any man, but our motor friend went on, and the humor of the thing so struck many of his customers that instead of waiting thirty days, they sent him in their checks at once, congratulating him upon his remarkable display of zeal and enterprise. An episode of this kind carries with it the moral that it is never out of season to sell and install electrical apparatus.

The Edison-Lalande Battery.

Though Mr. Edison has devoted most of his time for the last 10 years to the perfection of apparatus for the generation and utilization of heavy electric currents, he has recently turned aside to take up a branch which has by many been neglected in these later days. The primary battery has, indeed, come to be considered much in the nature of a necessary evil, and perhaps not seldom justly so. But being still a necessity in a vast number of situations, it merits attention and ought not be considered slightingly. With these sentiments in mind, evidently, Mr. Edison has taken up a type of battery which undoubtedly possesses some marked characteristics that for certain purposes makes its application advantageous notwithstanding its comparatively low E. M. F. The improvements effected in the cell over the form as originally brought out by Lalande, will go far towards introducing it in places where its application was formerly impracticable.

The Senate Committee's Report.

It must be a matter of satisfaction to all who are interested in the welfare of the electric light and power industry that the New York Senate Investigating Committee, charged with the duty of reporting on the relative dangers of overhead and underground wires, and high and low tension currents, has submitted a quite reasonable and moderate statement of the case. Where a body of this kind is so endowed with the ability to do mischief, it is cause for congratulation that it cultivates rather the opportunities of allaying public fears and of presenting the evidence in a straightforward, re-assuring manner. In the main, the report which we print elsewhere is excellent. The chief point to which we would take exception is the proposition that no overhead electric railway wires shall be run in cities of over 125,000 population. The direct current on such wires of 500 volts is not dangerous to life, and with proper construction does not endanger property. Should the proposed limitation be adopted, however, there would, we think, be a very rapid development of storage car work and of conduit systems, and this, certainly, would be something that could be viewed optimistically.

Passengers Per Car Per Month.

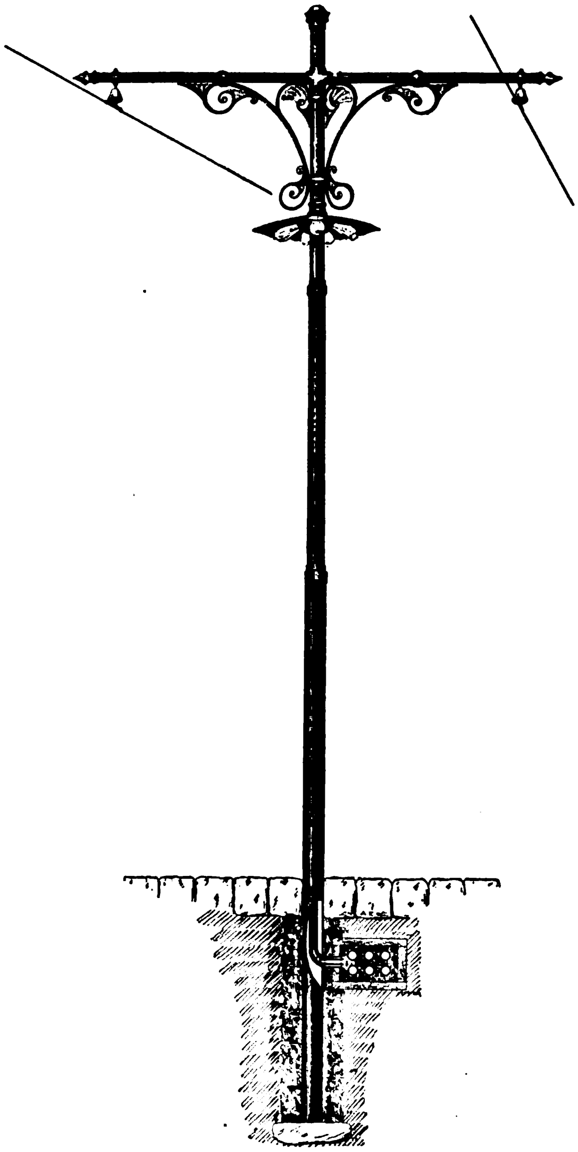
The question is often asked : "How many passengers do street cars carry ?" On this point there has been no little figuring and conjecture; yet like most things of the kind it should be easily determinable. Looking into the matter not a great while ago, the Thomson-Houston Company found that 9,000 passengers per car would be a fair average for good, ordinary work. This figure was arrived at from reports on a number of their electric roads operating only from two to ten cars. This would make 300 passengers a day for a month of 30 days, and would represent, say, $15 daily in fares. We would be glad to hear from some of our readers on this item of receipts, which is naturally a vital one to managers contemplating a change of motive power or to capitalists starting a new road. It has been estimated that the electric roads of the country are carrying now about 150,000,000 passengers a year. Upon the basis of 9,000 per car per month, and 2,000 cars in operation this summer, electric roads during 1890 will be carrying passengers at the rate of $16,000,000 per annum.

Electricity and Social Science.

It is interesting to note the manner in which the leaders of thought to-day look to electricity for a solution of many of the problems that they grapple with hopelessly or despondingly under the old familiar conditions. One hardly expects their fond anticipations to be fully realized, but there should be encouragement for electricians and electrical engineers in this recognition of them as the vanguard of the social and industrial influences that make for progress and a higher evolution of human existence. In fact they are under the responsibility of having to prove almost more than any other body of men that science, invention and discovery tend to promote the welfare of modern society. In this issue will be found a paper which, dealing with electric railroads as the latest practical development of electric arts, endeavors to set forth the various advantages that may be derived from this form of locomotion in towns and cities. Perhaps there is not much that is new in the paper, nor much that lies far below the surface, but it may be helpful in suggesting to the public some of the benefits it will secure, and in supplying the electric railway engineer and promoter with arguments for his campaign.

NEW SPRAGUE RAILWAY UNDERGROUND WORK.

When electric railway work was first undertaken, the number of cars and the distance covered were so small that a single conducting wire overhead sufficed both as the feeder and trolley wire, or working conductor. As the number of cars operating upon a single road, as well as the distance of the lines radiating from the generating station, increased, it became apparent that the drop and the loss in the line consisting of a single trolley wire were too great. To increase the size of this wire, however, involved a number of difficulties, and, as a result, the practice was inaugurated of running what are known as main conductors in connection with the trolley wires which are designated the working conductors. These main conductors of heavy wire are usually attached to the same poles as the trolley wires, and are connected to the latter at short intervals. At various points also, in the best designed systems, they are connected to heavy feeders radiating from the central station, so as to maintain uniform potential on the line.



Electric Railway Pole and Conduit Connection.

Essential as these main conductors are to the proper operation of the system, their presence overhead, has given rise, on account of their necessarily large size, to some objections, and it is with the purpose of removing these that the Sprague Electric Railway and Motor Co. has designed a system in which only the trolley wires appear above ground, all other auxiliary conductors being placed underground.

The accompanying engraving shows in general the plan which it is proposed to adopt in future work of this kind in densely populated districts.

The work intended contemplates the placing of poles for carrying double trolley wires between double tracks of the street railway. The mains and feeders are to be carried in insulated conduits placed underground. The subfeeder wires between the main line and the trolley line, will be carried up the interior of the pole in an insulated or interior conduited pipe. Another set of wires for lights will also be supplied from a separate switching circuit running direct from the station and connected with all the series of lights on the poles. The conduits employed will probably be those manufactured by the Interior Conduit and Insulation Co. The details of this system give a very excellent form of construction for electric street railways making the overhead system entirely unobjectionable, and furnishing also the light for the streets through which the railway passes, the control of the lights being from the power station direct.

THE NEW WESTINGHOUSE ALTERNATING ARC LIGHTING SYSTEM.

As our readers may be aware, the Westinghouse Electric Company have for some time past been engaged in working out a system of arc lighting with alternating currents, and the results obtained have been such that the system is now ready to be placed in commercial operation. One of the first systems of arc lighting, which was commercially exploited, it will be remembered, was that of Jablochkoff, who as far back as 1876 employed his well known candle in direct circuit with a dynamo machine which generated alternating currents. The present system, however, is designed to be operated generally in connection with converters.

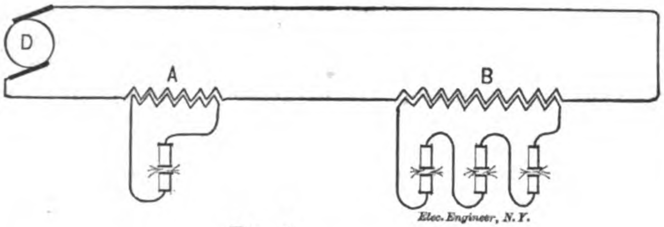


FIG. 1.

The system, broadly speaking, consists in operating a constant current main circuit which passes through converters suitable for the number of lamps to be operated at any one point. The diagram, figure 1, shows this method of operation in outline. Here the dynamo, D, generates a constant alternating circuit which, passing to the primaries of the converters, A and B, generates in each the current sufficient to operate one, three or more lamps, as the case may be. The system has been worked out in a very complete manner both as regards the dynamo, the lamps and accessories.

Beginning with the dynamo, which is illustrated in the engraving, figure 2, it will be seen to resemble very closely the Westinghouse alternating incandescent machine, but its distinguishing feature is to be found in the construction of the armature. The latter is shown in perspective in figure 3, and in longitudinal and transverse sections in figure 4. It will be noted that in this case the armature coils are not, as heretofore, in the shape of flat coils placed on the periphery, but consist of oblong coils which are wound separately as shown in figure 5, and then by means of the clamping tool, figure 6, are clamped in position around the cores of the armature projections which are provided with overlapping teeth. After the coils have been placed in position the spaces between the teeth are filled out with

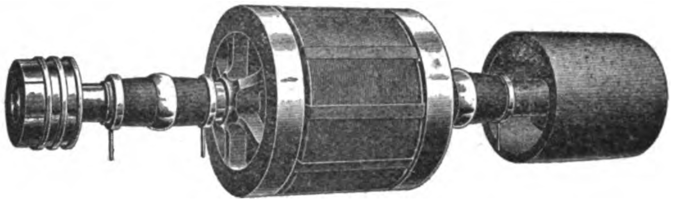

FIG. 3.

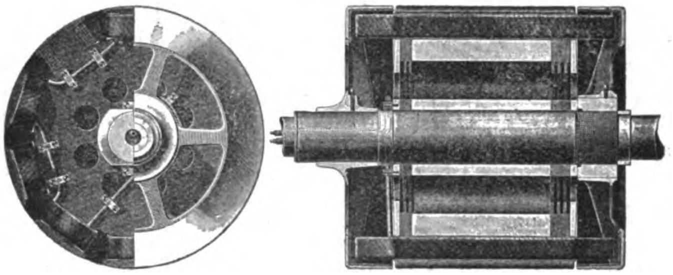

FIG. 4.

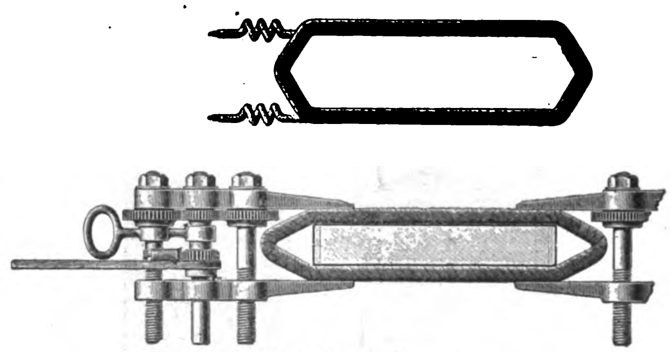
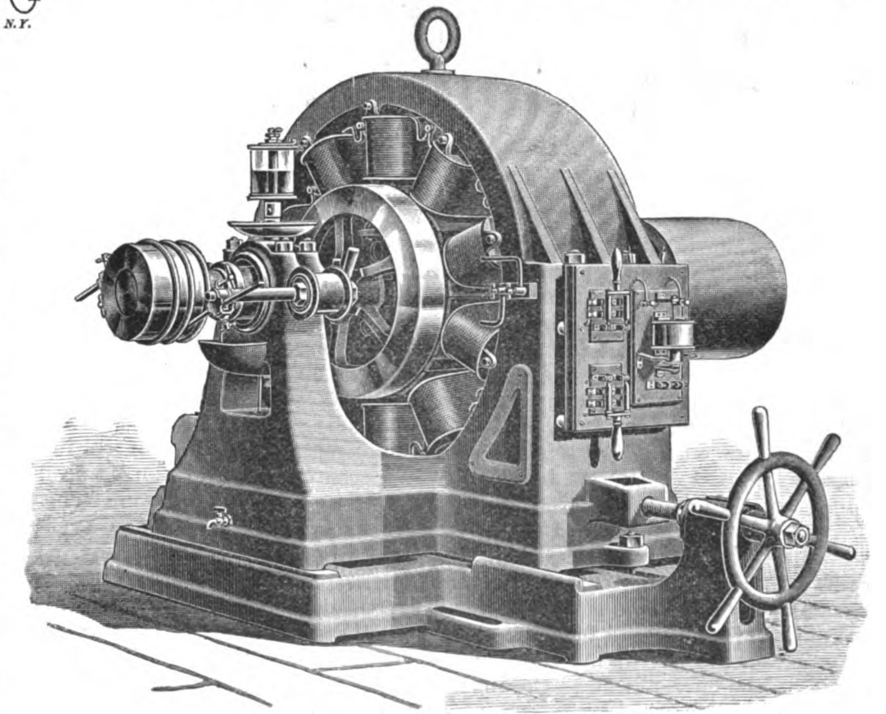


FIGS. 5 AND 6.



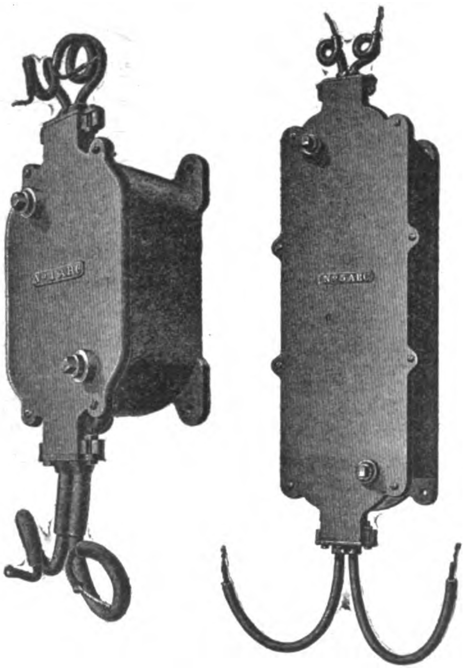
THE WESTINGHOUSE ALTERNATE CURRENT ARC MACHINE.

wooden wedges which are dove-tailed and slid in from the side, so that no further fastening is required to keep the coils or the wedges themselves in position.

The peculiar construction of the armature with the overlapping teeth has the effect of maintaining the current constant at all loads, so that there is no regulating apparatus whatever required for that purpose.

The armature is built up of thin wrought-iron sheets stamped out to the required shape and the teeth are so designed, and are of such length, that they slightly overlap the distance between two consecutive pole pieces, so that one tooth is not out of the field of any one magnet before another enters that field.

At the side of the dynamo in figure 2, there will be noted an apparatus consisting of a solenoid with a single core. It is a short circuiting apparatus, and its object is to protect the machine from the results of a break in the line. In the continuous current machine a break in the line is generally followed by the cessation of current in the armature when a series machine is employed; but in this system a break in the external circuit causes the generation of a heavy current in the armature, which, if not prevented, would eventually cause its destruction. To avoid this the apparatus shown is employed and its function is to short circuit the armature. By this means the counter electromotive force generated in the armature is such as to cut down the heavy current to the normal strength, so that no dangerous heating of the armature coils can take place. The apparatus is so constructed that an excess of electromotive force generated in the armature, such as would be caused by a break in the line causes a spark to pass between two points; this allows sufficient current to pass to energize the solenoid which pulls up its core and makes contact between two points that short circuit the armature. Normally the distance apart of these points is so regulated that any excess of current beyond 12 amperes causes the spark to jump and effect the short circuiting.



FIGS. 7 AND 8.

There is still another safety device of the same nature which consists of two metal points placed opposite each other on the armature shaft and connected respectively to the collector rings. Upon the current exceeding a certain value the spark formed between these two points causes a short circuiting of the machine and a consequent cutting down of the current due to the increased self induction.

The machines now built and in course of construction vary in capacity from 25 lights to 240 lights, and the table on page 152 shows their various sizes and capacity. It will be noted that the speeds of these machines are considerably lower than those employed in the incandescent system and that the number of alternations per second is also far below that of the former, the average number approximating 7,500 alternations per minute, as compared with 16,000 for the incandescent machines. The machines Nos. 2 and 3 are provided with two sets of windings connected to two pairs of collectors, so that two independent circuits can be run from one machine.

Coming now to the apparatus intermediary between the dynamo and the lamps, we find it to consist of converters which do not, of course, differ in principle from those used in connection with the incandescent system of distribution; but for this particular purpose converters of a peculiar construction are in some instances desirable. In ordinary incandescent systems the primary and secondary of the converter are usually so designed that the ratio of reduction of potential between them is comparatively a high one, usually in the neighborhood of 20 to 1. In this system, however, a series of converters of various capacities are designed in which the ratio of the primary to the secondary is as 1 to 1, and in others as 1 to 3, as exhibited in the table, on page 152, of the various sizes constructed. Two sizes of these converters are illustrated in figures 7 and 8. The windings in the 1 to 1 converters are evidently identical for the primary and secondary. Though on first consideration this might be considered a curious condition, the reason therefor will become apparent when it is considered that by the employment of such converters no greater potential is admitted to a building in which there is one lamp, for instance, than is required for that particular one, and leaving the same perfectly safe to be handled, as the potential required for each lamp does not exceed 50 volts.

The lamps employed in connection with this system are of two general types known as the long and short lamps, and designed respectively for outdoor and indoor use. The long lamp is shown in figure 9, as it appears when trimmed, and figure 10 shows the same ready to be trimmed, a very simple device being attached by which the globe can be conveniently hung from the lamp while the operation of trimming is proceeding. The short arc lamp, which does not differ in its principle of construction from that just described, is designed for indoor use and is usually provided with white globes.

The distinguishing feature of these lamps consists in the fact that they are designed to burn carbons whose life approximates to 40 hours in the case of the long lamp, and to a somewhat shorter period in the case of the short lamp. Thus, in the long lamps two carbons are employed, the dimensions of which are 9½ x 2 x $\frac{7}{16}$ inch. Both carbons are of the same dimensions, as the alternating currents have an equal action on both. In the short lamp the length of the carbon is reduced to six inches. The mechanism of the lamp is very simple and consists in a rack movement which is regulated by a solenoid in the main circuit and by another of high resistance which is placed in shunt to the arc. Both of these are provided with cores built up of bundles of fine wire so as to avoid heating and to increase their sensitiveness. The lamps may be operated in connection with electric meters and in this way the customer may control individually the time during which the lamp shall burn and at the same time the charge which is made for the same. The employment of carbons lasting in the neighborhood of 40 hours also obviates the necessity of a daily inspection and trimming of the lamp. The lamp when burning is accompanied by a slight humming noise, which, however, is hardly noticeable, and which we understand will soon be overcome.

There are several excellent accessory devices employed with the system, one of which, a double safety cut-out, is illustrated in figure 13. This consists of the usual strips of fusible metal but, in addition, the points which they span are shunted by a fine German silver wire. It frequently happens that upon the fusing of the usual safety strip, an arc forms at the break which is apt to travel backward and burn the contacts and thus ruin the entire device before the arc is broken. By employing the German silver shunt around these points the fusing of the fusible strip immediately sends the current through the shunt which at once fuses, breaking into small pieces and forming directly a break of six inches between its terminals—a distance which the arc is incapable of following.

Our readers will no doubt be interested in a series of tests which have been made on this system showing its efficiency under various conditions and for that purpose we add below a table giving the results of a test carried out at the works of the Westinghouse Electric Company in Pittsburgh. These tests were made on a No. 2, 30 ampere machine operating 120 lights. The engine was of the Westinghouse single acting two cylinder type, the diameter of the cylinder being 14½ inches and the length of stroke 30 inches. The curves shown in Fig. 14 represent graphically the results given in the table. From these it will be seen that the machine at very light load has a comparatively low efficiency, but beginning with 40 lamps up to the full capacity the efficiency rapidly increases until at full load, it approximates 87 per cent. and the energy per lamp required is .75 h. p. A number of these machines have already been put in practical operation in this city and others are in course of installation in Boston, Portland and a number of other cities.

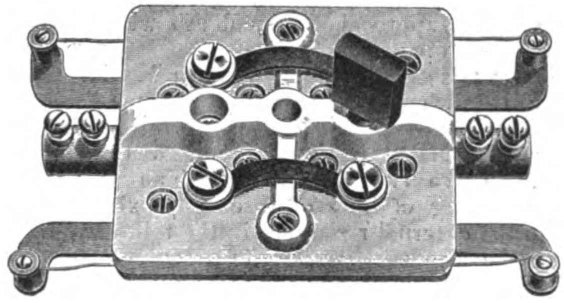

FIG. 13.

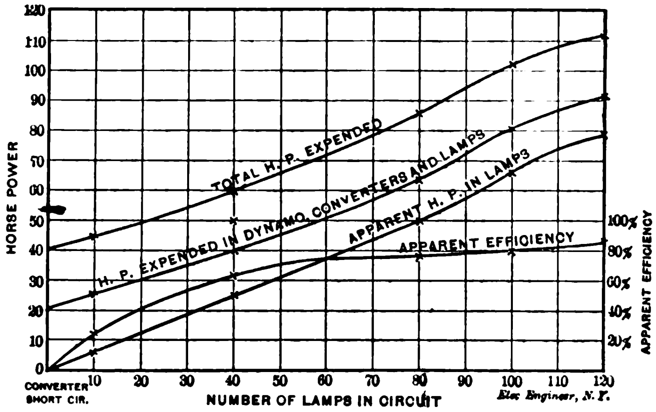

FIG. 14.

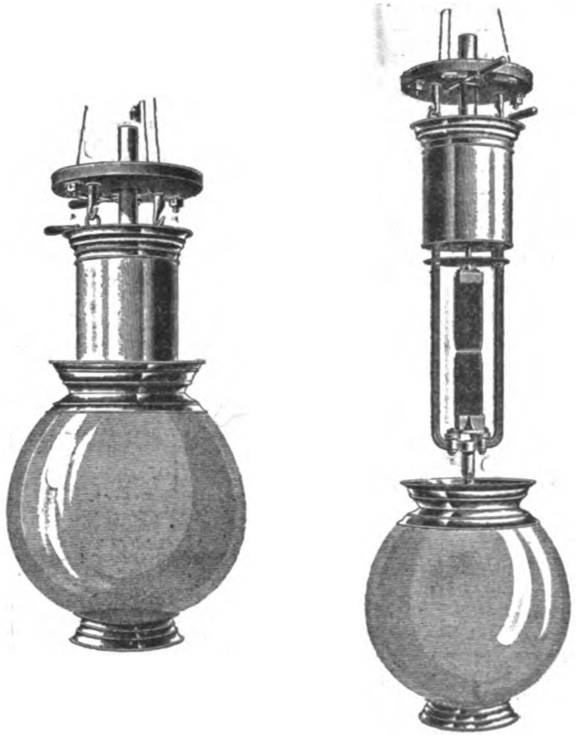

FIGS. 11 AND 12.

In further explanation of the action of the machine we may add that the regulation for constant current depends primarily upon the fact that the armature is wound with a sufficient number of turns to produce a high self induction, and consequently a lag in the current approaching 90 degrees when short circuited. According to a well-known law, the current lag, as related to the impressed electromotive force, is reduced by the introduction of resistance into the circuit, and approaches coincidence with the phase of electromotive force as its limit.

The magnetization of the field is so related to that of the armature that when an armature pole is opposite to a field pole and the magnetizing effects are in contrary directions the resultant magnetization is reduced to a very small amount. These two elements combine to produce an effective cutting of lines of force approximately proportional to the external resistance in the following way:

When the armature rotates with a high resistance in circuit the lag is small, and the maximum current flows in approximate coincidence with the maximum of electromotive force; that is, when an armature pole is in an intermediate position between two field poles. The direction of current is opposite to that in the field coils of the pole it is approaching. In other words, the maximum point in the current phase occurs about 90 degrees in advance of the coincidence of two poles of similar polarity.

A reduction of resistance in the work circuit causes a lag in the current phase, so that the maximum point is reached at an instant in time more nearly coincident with the opposition of similar poles; and when the armature coils are short circuited and the lag reaches its maximum, the magnetization of the armature pole occurs approximately at the time of its passage under a field pole of opposite polarity. Since the windings of the field and armature are such as to set up approximately equal magnetic potentials in opposite directions, the cutting of lines of force is now reduced to a minimum value sufficient to cause the flow of a normal current through the coils. The current characteristic of the machine can be made to approach as nearly to constancy as can the electromotive force characteristic of a constant potential dynamo with varying current.

SCHOOP ON ACCUMULATOR THEORIES AND MANUFACTURE.

At the meeting of the Chicago Electric Club, on March 3, Dr. Paul Schoop, of Zurich, Switzerland, read a paper on "A Theory of Accumulators." He combated the sulphate theory and advanced a view of his own. Speaking of an experiment with a palladium voltameter, Dr. Schoop made the following statement which gives an idea of his theory:

"We may say in short that the whole behavior of a palladium or of a platinum voltameter is in every way so similar to that of a lead accumulator that we would be at a loss to point out essential differences. The hydrogen is supposed to be held in the palladium, as, for example, mercury in copper or zinc, and physicists speak nowadays of an *alloy* of palladium and hydrogen. I now propose the following theorem: 'The charged kathode of a lead accumulator contains an alloy of lead and hydrogen, and this hydrogen-alloy is the true active material.' If platinum, palladium, mercury and iron combine with hydrogen, why should not lead do the same? Take a charged, so-called 'negative' plate out of an accumulator cell. After a few minutes vapors will rise from it and soon the plate will become so hot that the solid metallic frame will melt. Who can help remembering Faraday's platinum foil? Lead may be prepared in a most finely divided state, by reducing lead salts, say, chloride of lead or zinc, in an acid or salt solution; but this lead would not heat spontaneously as in the first experiment. We can easily see how the charged lead accumulator acts; the kathode contains hydrogen alloy and between it and the acidulated water there is a certain potential. The anode contains oxygen, however, not in a condensed state or as an alloy, and not firmly united, but in a chemical compound, namely, that dark, black, most highly oxydized peroxyde of lead. * * * Now what is our experience in manufacturing accumulators with pasted plates? The capacity of the cells depends directly upon the degree of fineness of the powder employed for the paste. Lead sponge obtained, for example, by heating tartrate of lead can absorb more hydrogen than can lead sponge obtained by reducing oxide of lead. The highest capacity is found in lead sponge in which all the particles are most finely divided within the largest space. If we press lead sponge under a high pressure, we find a decrease of its capacity, and if we finally press it into a solid plate of lead, we will have to commence again with the old Planté forming-process."

.... WE must depend for the rapid advancement of physical science upon the education of the masses. In this country, men devoted to science purely for the sake of science are, and must be, few in number. Few can devote their lives to work that promises no return except the satisfaction of adding to the sum of human knowledge.—*Professor W. A. Anthony.*

THE EDISON-LALANDE BATTERY.

It is several years since the attention of electricians was drawn to a battery invented by M. Lalande, which at the time attracted considerable attention on account of its simplicity and other advantages, principal among which was its constancy of action and low internal resistance. Recently Mr. Thomas A. Edison has taken up this type of cell and after considerable experimenting has succeeded in developing it into a form such that it can be generally applied to a large variety of work.

The elements employed in the cell are zinc as the positive, and the black oxide of copper, Cu O, as the negative, the exciting liquid being a solution of caustic potash. The black oxide of copper is obtained by roasting copper turnings; the oxide in the form of a fine powder is then compressed into solid blocks which are held in position in the cells by means of a light frame of sheet copper; the latter also carries the terminals at its top, as shown in the accompanying illustration, Fig. 1, which represents the 300 ampere-hour cell. The copper oxide element of the cell is placed between two rolled zincs which are superficially amalgamated and are prevented from touching the negative element by vulcanite buttons and rubber bands. As in most batteries, action upon the zinc is greater near the top; hence the zincs are made slightly tapering with the thinner end at the bottom of the cell.

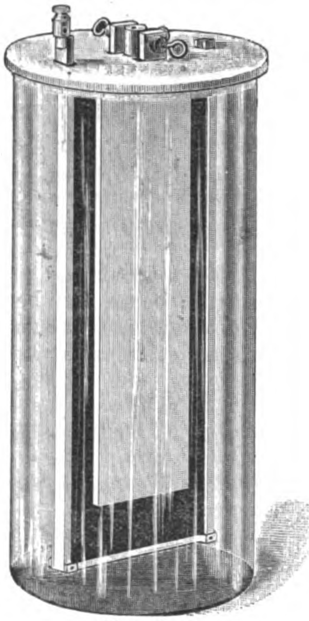

Fig. 1.

The solution employed in the battery consists, in the case of the 300 ampere-hour cell, of one pound of caustic potash dissolved in three pounds of water. The result of the action of the cell is to reduce the copper oxide to metallic copper, a double salt of zinc and potash being formed which goes into solution. This reduced copper is of great purity and can be re-employed by oxidizing it; and arrangements have been made by which the manufacturers undertake this work.

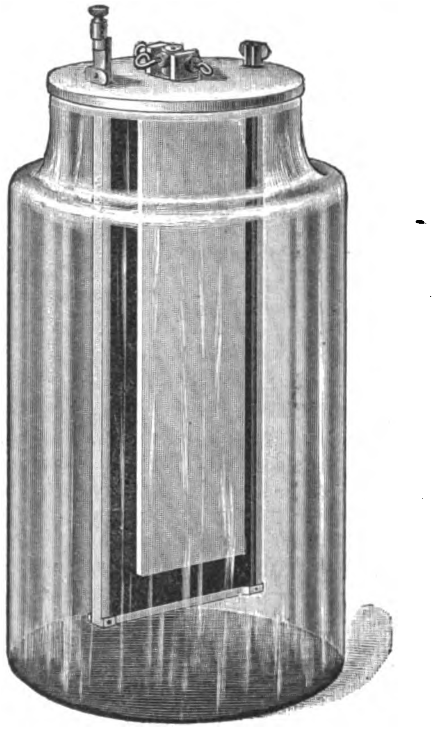

Fig. 3.

The most remarkable properties of this cell are its low internal resistance and its great constancy, which make it equally available for both open and closed circuit work. As an example we may cite the 300 ampere-hour cell which, standing 11¼ inches high by 5⅝ inches in diameter, has an internal resistance of only .05 ohm. The E. M. F. of the cell on continuous hard work is .7 volt, and on light work

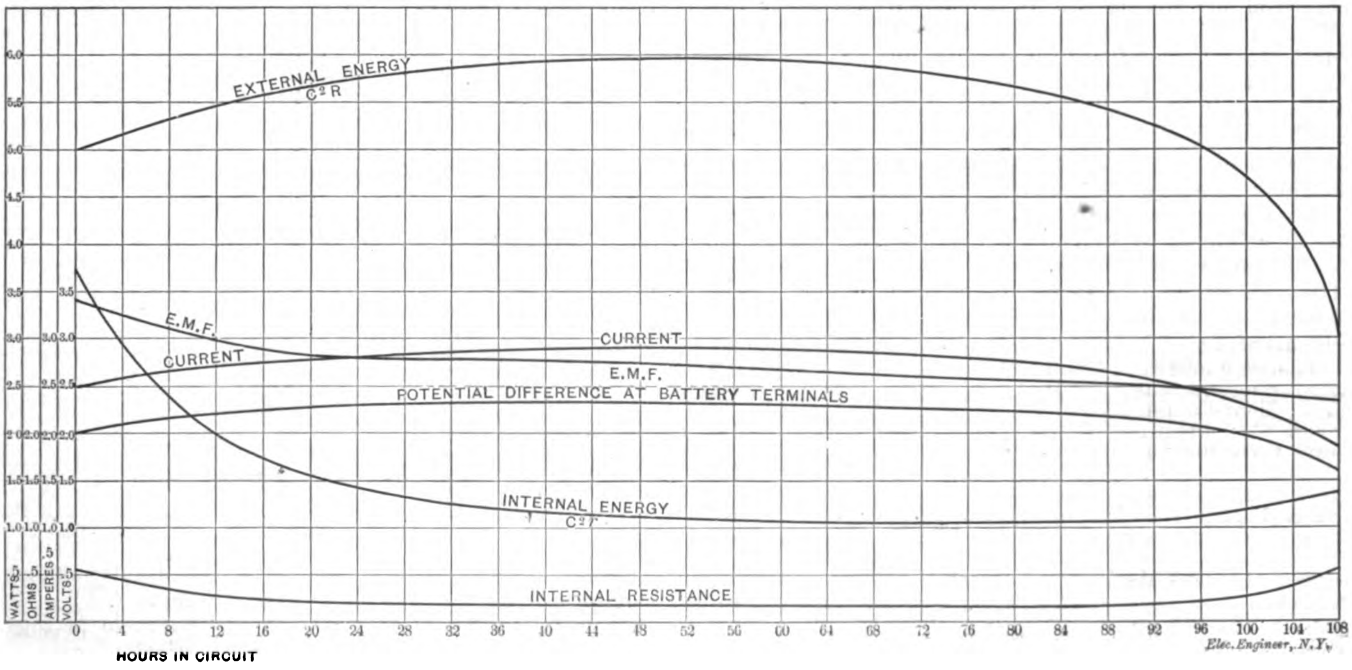

Fig. 2.—Curves Showing Action of Edison-Lalande Battery.

.75 volt. Its initial E. M. F. is .9 volt, but soon falls to the normal, where it remains practically constant during the life of the cell. On short circuit the cell is capable of delivering 14 amperes, while on open circuit there is practically no action on the zinc, and none whatever when the latter is pure.

The action of the cell is admirably shown in the accompanying curves, Fig. 2, which represent the results of very careful tests made at the Edison laboratory upon cells picked out at random from a large number. In this test four of the 300 ampere-hour cells were joined in series and gave the following results :

Weight of zinc before test,	10,017	grammes.
" " after "	8,567	"
Total loss,	1,450	"
Calculated loss from output,	1,444	"
Loss by local action,	6	"
Mean current, - -	2.76	amperes.
Total run, - -	298	ampere-hours.

The loss was calculated as follows, taking the chemical equivalent of zinc as 0.0003367, based on the latest concurring results of Rayleigh and Kohlrausch:

$$2.76 + 108 + 3600 + 0.0008{,}367 = 361; \quad 361 + 4 = 1444.$$

The test, as shown, extended over a period of 108 hours, and both the current and E. M. F. remained practically constant. It will be noted, however, that the external available energy continued to increase for nearly half the period of the test, owing to the almost constant decrease in the internal resistance of the cell, which is also evidenced by the curve representing the internal energy, which falls rapidly from the start. This decrease in internal resistance is due to the fact that the reduction of the oxide to metallic copper at the surface of the negative plate presents an excellent conducting surface, but requires a few hours work in a cell freshly set up. In reading the figures at the left, those referring to the watts, ohms and volts must be divided by four in order to reduce them to the corresponding values for a single cell. During the test the cells were in circuit with a resistance of .8 ohm.

The character of the cell, as outlined above, adapts it to a large variety of work. Thus in telegraphy it can be used as a main line battery, where its low internal resistance permits of operating a large number of lines from it without loss of power, especially in wet weather. For operating locals, also, this quality makes it possible to operate as many as twelve sounders from a single battery consisting of three cells. In an actual test made in the Western Union Telegraph Building in this city three cells furnished current for 15 sounders during 105 working hours. On account of its great constancy, too, the cell is well adapted for small motor work, such as driving sewing machines and other light apparatus; 10 cells of the 300 ampere-hour type being sufficient to operate a sewing machine motor for 40 hours.

For open circuit work the constancy and low resistance of the cell make it well adapted for telephone transmitters, electro-medical apparatus, annunciator work and the like. The cells are manufactured in a number of sizes, ranging from 15 ampere-hours to 900 ampere-hours capacity. The 600 ampere type is shown in Fig 3.

We may add that the manufacture of this cell has been undertaken on a large scale by the Edison Manufacturing Company, special works having been erected for that purpose at Spring Lake, N. J.

THE HUNTINGTON SEARCH LIGHT AND PHOTO-ENGRAVING LAMP.

At the late Maritime Conference held in Washington, attention was drawn to a new form of marine search light embodying several novel features. The Huntington search light, as it is called, is shown in the accompanying engraving, Fig. 1, and consists of a parabolic reflector, containing a series of condensing plano-convex lenses. The lamp employed is of the automatic focussing type and is designed to be run in connection with any constant potential low voltage circuit. The reflector and lamp are enclosed in a waterproof casing and can be turned through any angle in a vertical plane, while the standard upon which the casing is mounted can be turned through any angle in a horizontal plane. As a result, the beam can be directed upon any point between the horizon and the zenith. The employment of the condensing lenses effects a concentration of the beam and prevents its spreading, which usually cannot be avoided even with the most perfect reflectors.

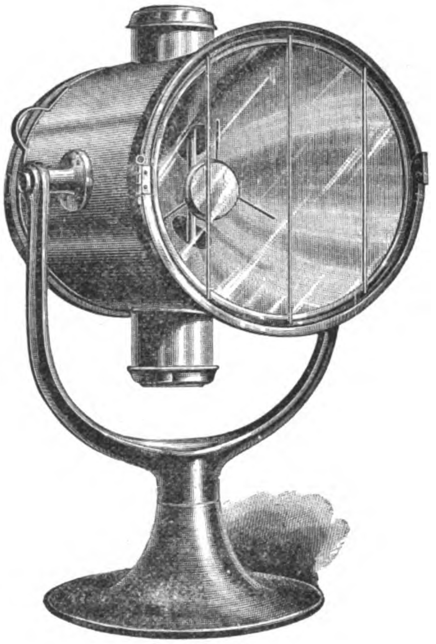

FIG. 1.

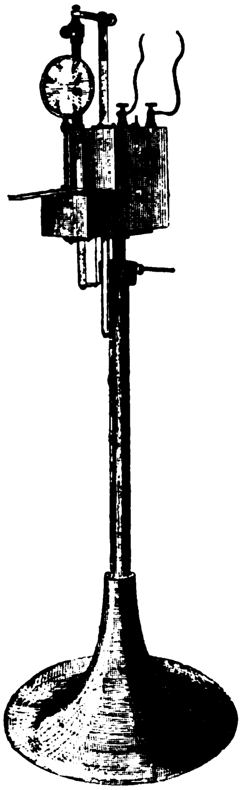

FIG. 2.

These search lights are specially valuable in fogs on board ship, where a beam thrown vertically into the air illuminates the fog and distinctly marks the location of the ship carrying it. This has been proved to be of great value on some of the large steamers plying on the Long Island Sound. Among the other vessels recently equipped with this search light are the steamers "Umatilla," of the Oregon S. S. Company; the "Piedmont," of the Central Pacific Railway Company, running in San Francisco Bay; and another is about to be placed on board one of the Claus Spreckels S. S. Line vessels at San Francisco.

The Scott Electrical Works, of this city, the manufacturers of this apparatus, have also recently brought out an electric arc lamp outfit specially designed for photographic and photo-engraving work. The lamp which is shown in the engraving, Fig. 2, is designed to be run from a constant potential low voltage circuit and is mounted upon an adjustable stand which can be easily transported and moved about. The lens provided enables the operator to enlarge or diminish the area of focused light from a mere focal spot to a circle several feet in diameter, according to the size of the work to be photographed or printed. In this way the wide and general dispersion of light is obviated, and the illumination concentrated exactly upon the point where it is desired. Apparatus of the kind just described is now installed in the workshops of the Star Engraving Company and the New York Electro Light Engraving Company in this city, making the progress of the work in hand independent of sunlight.

THE MICHALES ELECTRIC MINING MACHINE.

The advent of electricity in the mining regions holds forth a promise of the solution of many problems in the transmission of power that have heretofore taxed the ingenuity of miners and engineers. In the coal mining regions especially the great power which can be developed by the compact electric motor without any of the accompaniments entailed by the use of steam has engendered a lively interest in the design of mechanical coal diggers to be operated by electric motors. Among the most recent of these to be brought to the attention of the public is that invented by Captain M. A. Michales, of Pittsburgh, Pa., which he was aided in perfecting by Dr. O. S. Weddell, of McKeesport, Pa.

The machine is illustrated in the accompanying engraving, Fig. 1, which shows the casing in section exposing the working mechanism; Fig. 2 being an end view. The machine when ready for work stands nine feet in length, one and one-half foot in breadth and two and one-third feet high, and weighs about 850 pounds. It is supported on sliding axles for the purpose of balancing the machine when a shorter or longer pick is used, and is provided with a two horse power Tesla motor, from which the power is transmitted through a combination of gear wheels, B, C, E, and shafting, D, to a cam, F, surrounding the drill bar, I. Within this cam on the drill bar there is placed a thumb, *b*, Fig. 2, on the end of which is a small trolley wheel, *a*, which turns and prevents friction as the cam passes in front of it. By the rotation of the cam its inclined surface passes in front of the trolley wheel, forcing it back and up the incline, drawing with it the drill bar, I, against the tension of a powerful spring, K, which encircles it. The backward motion continues until the vertical wall of the cam, F, passes beyond the trolley wheel, when it is automatically released and forced violently forward by the action of the spring, K, the trolley wheel returning to the bottom of the spiral incline.

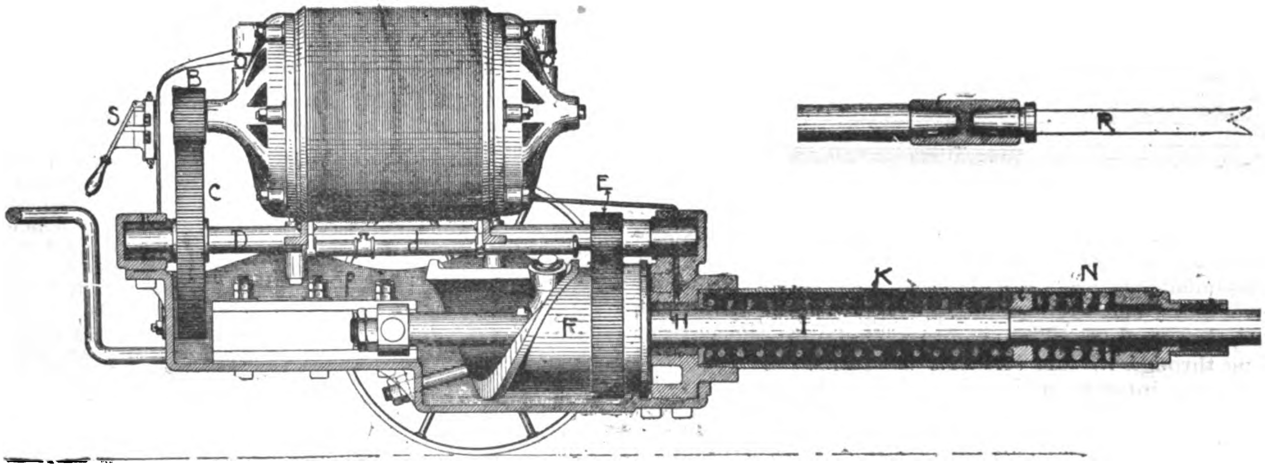

FIG. 1.—THE MICHALES ELECTRIC MINING MACHINE.

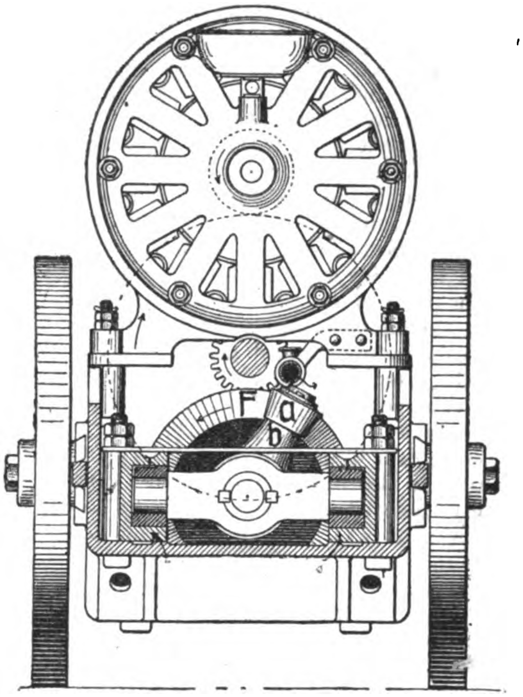

FIG. 2.

In order to relieve the shock to which the machine would be subjected in case the pick should not strike against the coal, there is a very powerful spring, N, interposed between the shoulder, M, on the drill bar and the front end of the tube, L, which surrounds it. The springs, K and N, constructed especially for this machine, are of different tension, and can be changed in a moment, as the character of the work requires.

The machine strikes one hundred and twenty blows per minute, and with a force of 9,000 pounds to the blow.

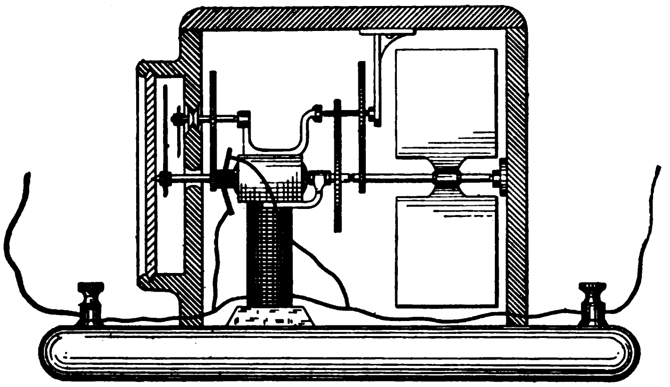
A special feature of the machine is, that at whatever point in the stroke the pick is arrested it is instantly returned from that point ready for the next blow; and when the blow is delivered, even though it be arrested in its course, instead of the machine pushing itself away from the coal as one would naturally suppose it would do, it is said rather to incline toward the coal owing to the momentum of the drill bar.

In working the machine the operator places each blow, as would the hand miner, where it will be most effective, cutting from four to six feet deep. This cut is made on a level with the floor, being of a V-shape, eight inches in front and tapering back to two inches in the rear, making an average cut of five inches. When the under cut is made the operator in like manner can shear the end. One great advantage of this V-shaped cut is that, when the coal falls it will roll over and out of its original position where it can be very advantageously loaded. It requires one man and helper to operate the machine.

To convey the current from the dynamo at the entrance of the mine to the motor on the machine, well insulated wires are strung along the side of the entries near the roof, being fastened to the props or plugs placed in the coal for this purpose. Switches are placed opposite the entrance to each room in order to facilitate the changing of the machine from room to room. Wires are coupled to the main circuit in the entry to convey the current to the machine.

The Tesla motor, manufactured by the Westinghouse Electric Co., has been adopted for operating the machine. This motor is peculiarly fitted for mine service owing to its compactness in design and simplicity of construction. The absence of commutator and brushes allows the armature, which is the only moving part of the motor, to be completely enclosed and protected from mechanical injury. No regulator of any kind is used, and the only piece of apparatus in connection with the motor is a simple switch. The machine, which is built by the Michales Electric Machine Co., of Pittsburgh, Pa., has been thoroughly tested in the hardest coal in Western Pennsylvania, and the results have been of a most gratifying nature.

THE EDISON "MOTOR" METER LITIGATION.



Early Edison Motor Meter.

As recently announced, suit has been brought by the Edison Electric Light Co. against the United States Illuminating Co. of New York, one of the lessees of the Westinghouse Electric Co., of Pittsburgh, Pa., for infringement of one of Mr. Edison's early patents on an electric meter embodying as its principal feature an electric motor, the speed of which is proportional to the current passing through it. As the suit in question has aroused considerable interest in electrical circles on account of its possible effects now that currents are so generally metered, we give below an extract from the patent specification and one of the drawings to which it refers. This patent was issued to Mr. Edison on June 14, 1881, and was preceded only six weeks by the original "weber-meter" which took the form of an electrolytic balance the oscillations of which operated a recording device.

In describing his invention, Mr. Edison uses the following language :—

Generally speaking, it (the meter) consists of a motor, to which is given a certain definite amount of work to do or resistance to motion to be overcome, combined with registering devices which register the amount of work done or resistance to motion overcome.

I have found that the rapidity with which the motor will accomplish its work with a definite loading is proportioned to the amount of current energizing it. Hence, if the motor be arranged to have a slow motion when the amount of current necessary for, say, one translating device passes through the circuit, its speed will be increased proportionately as the number of translating devices using current is increased.

The motor may be placed with its field and armature coils both directly in the main circuit or both in a shunt-circuit. The field-coils may be placed in the direct circuit and the armature in a shunt thereto.

The loading or resistance may be given in a variety of ways. For instance, fan-blades or wings may be connected to the armature-shaft by multiplying gearing ; or, preferably, blades or wings may be driven in a tank or dash-pot filled with a thick liquid—such, for instance, as are used in gas-meters—by slowing down gearing or worm and screw, so that the movement of the registering devices is much less than that of the actuating rotating armature.

We give also the claims which are embodied in the patent, as follows :—

1. The combination with an electric circuit containing translating devices of an electric motor having a definite loading and apparatus for registering the work done, substantially as set forth.
2. The combination of an electric circuit, an electro-motor, a fan driven thereby, and a registering apparatus, substantially as set forth.
3. The combination of an electric circuit, an electro-motor, a fan or blades driven thereby, a vessel or tank in which the fan or blades are placed, and registering apparatus, substantially as set forth.
4. The combination of an electric circuit, an electro-motor, a fan or blades, a vessel or tank filled with liquid, in which the blades or fan are placed, and a registering apparatus, substantially as set forth.
5. An electric meter consisting of a motor having a definite work to perform or loading to overcome, and registering devices, substantially as set forth.

In the complaint filed by the Edison company it is alleged that the well-known Shallenberger meter infringes the above claims.

Besides the form of motor meter described above, Mr. Edison also constructed one in which the principle involved in the operation of "Sturgeon's wheel" was employed. The armature of this meter which is still in existence, consists of a copper cylinder revolving between two pole pieces, and by employing mercury contacts friction is almost entirely avoided. As our readers are aware, however, Mr. Edison's experiments finally led him to adopt the electrolytic meter as the standard in his work and for commercial practice.

DEMONSTRATING ELECTRIC RESONANCE.

Dr. Lodge, in a recent number of *Nature*, describes a simple lecture experiment to demonstrate electric resonance. The oscillator consists of a Leyden jar, whose inner and outer coatings are connected by means of a rather large loop of wire to two knobs placed near together so as to form a spark gap. The resonator consists of a similar jar whose coatings are connected by a loop of about the same dimensions, but the resistance of which may be adjusted by sliding a copper piece along two parallel wires connected up in circuit. An overflow path is provided for the second jar by means of a strip of tinfoil pasted over its lip and almost long enough to connect the two coatings. By adjusting the position of the slider, the second jar responds every time the first discharges. Professor Lodge finds that it is not necessary to use long sparks for these experiments, and that, in fact, the vibrations are steadier and more definite with short ones.

.... W. J. Macquorn Rankine introduced the word "efficiency" to denote the ratio of the useful work done by a machine to the whole work done.

.... Franklin's view that positive charge was excess, and negative charge was a deficit, in a certain standard quantity of electric fluid which all bodies naturally possessed in their neutral state, remains practically true.—*Oliver J. Lodge.*

ELECTRICAL ENGINEERS.

FRANCIS JARVIS PATTEN.

F. **Jarvis Patten**, late lieutenant of the United States Army, the subject of our portrait in this issue, was born at Bowdoinham, Maine, in 1852. He is the eldest son of the late Captain Jarvis Patten, first Commissioner of Navigation of the United States, and is a descendant of one of the oldest families of his native state, his great-grandfather having served there as a commissioned officer in the colonial forces before the Declaration of Independence.

From early youth Lieutenant Patten enjoyed exceptional educational advantages. His father having decided for him a professional career, his preparation for it was urged with such dispatch that when a boy he complained of harder work and a more severe restraint while at home during vacations that when pursuing his regular course of study at school.

He developed at an early age a strong talent for drawing and constructive design, but for fear that he might become an artist all practice in this line was persistently discouraged, and he was put closer than before at Latin and the Classics, for which he displayed no great fondness.

When he was thirteen years of age business arrangements took his parents to Europe, and for the next four years he was kept at school on the Continent for further linguistic training, and returned to his native land at seventeen conversant with the French and German languages, and having also a slight knowledge of Latin, less of Greek and none whatever of the physical sciences. It was now time to choose a college course with a view to a professional career, and Cornell University, then a new institution, was chosen, more because of his deficiency in Greek than for any other reason. This chance selection proved fortunate, for at this institution he followed the scientific course and became an earnest student of subjects more congenial to his tastes. A frolic in the third year of his course severed his connection with this college, and while at home under sentence of suspension for a term he was offered and accepted a cadetship at West Point.

At the Military Academy he stood high in his class in all the scientific branches, and particularly in the engineering course. He was graduated and commissioned a lieutenant in the regular army in 1877, and from that time until 1887 his life was that of an army officer on the western frontier, where he participated in several Indian campaigns and engaged in much of that sort of engineering work incident to army life in the West. During this period he had much time for reading and study, and had never ceased to be a student.

On a visit to the eastern states in 1883 the marked development in all electrical applications which had really been brought to a practical value during his long stay in the West turned his attention to this subject, and he decided that in this direction lay the opportunity to apply the training to which he had given his best efforts. He set about at once to equip himself for this work and to familiarize himself with existing developments, as well as the new theories of this subject upon his return to the army, and devoted his spare time until 1887 to a study of the practical applications of the new science and its underlying principles.

So interested did he become in this work that he soon fell to inventing. His first effort in this direction was a "self-recording electrical target" designed for army use. It received some development and was put to a practical test, but was deemed too expensive and too radical a change for the service and therefore did not prove remunerative. Numerous minor inventions followed as his attention drifted to other applications.

It was, however, while investigating the peculiar properties of electric motors that he perceived the evident application of alternating current motors to synchronous multiplex telegraphy. If he was not the first to conceive this idea he was certainly the first to apply it, and by its use he has developed a system of synchronism that is self-corrective and has proved to be practically perfect, rendering possible an entirely new and original system of telegraphy by which twelve messages can be sent at the same time over the same wire without interference. Lieutenant Patten has brought this system, which involves many original ideas and applications, to a practical form in a remarkably short period of time, and besides this he has found time to produce and develop numerous other inventions of marked originality and novelty. Among these we may mention alternating motors of various forms, and a novel system of distribution by alternating curents, which admits of two applications not heretofore deemed possible, namely, the charging of storage batteries and the maintenance of a constant magnetic field by means of the alternating current which renders possible the construction of motors for such circuits, having all the characteristics of ordinary direct current machines.

Lieutenant Patten was married in 1883, and since his resignation from the army has resided in New York.

.... The more learned a person is, the more he is convinced that he does not know what electricity is.—*Professor John Trowbridge.*

.... The experience in New England has been that every gas company has increased its sales of gas since electric lights have been introduced.—*A. F. Upton.*

.... **Franklin's** view that the electric fluid was never manufactured, but was taken from one body to give to another, so that one gained what the other lost—no more and no less—remains practically true.—*Oliver J. Lodge.*

.... It is of the highest importance in a scientific point of view, as well as from the point of view of progress in material wealth, that the principles and details of science should be spread broadcast.—*Professor W. A. Anthony.*

SOME TESTS ON THE EFFICIENCY OF ALTERNATING CURRENT APPARATUS.[1]

BY DR. LOUIS DUNCAN AND MR. W. F. C. HASSON.

SEVERAL papers have appeared lately on the efficiency of alternating current transformers, some of which have been of a more or less theoretical nature, while others have given the results of actual tests. I have never, however, seen any tests on alternating current dynamos, excepting the experiments made by Dr. Hopkinson and Professor Adams on a de Meritens machine used for lighthouse work. Even the converter tests have given such varying results that one can hardly be certain as to the real efficiency.

The introduction of the alternating system has been so rapid and is so rapidly increasing that people are apparently well enough pleased with the results not to bother about the smaller question of the reasons for them. But whatever the results may be it is of value to know just where the losses in any system may come in, so that we may seek how to avoid them ; if we are succeeding, it may enable us to increase the profits,—if we are losing, it may help us to avoid further loss.

The apparatus, the measurement of which is the main subject of this paper, consisted of a Westinghouse 750-light No. 1 dynamo, with a No. 2 exciter and an outfit of 40-light converters. This apparatus had been presented by the Westinghouse Electric Company to the Johns Hopkins University, and was tested a couple of months ago. The workmanship of the machines is excellent.

The plant consisted of a 75 h. p. Armington & Sims engine driving the dynamo and exciter through a Tatham transmission dynamometer. Engine, dynamometer and dynamos were firmly secured to heavy parallel timbers which served as a foundation. The converters were banked on a wooden framework at a distance of some 30 yards from the dynamo, and their primaries were permanently secured to the dynamo circuit, a switch in the latter serving to cut them off when desired. The ammeter belonging to the plant was put in this circuit and was read when efficiency measurements were being taken. The secondaries of the converters were taken to a switch-board and then to incandescent lamps mounted on racks.

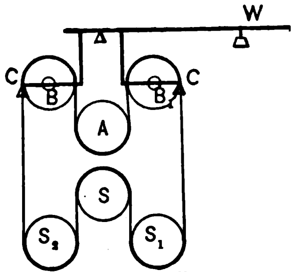


FIG. 1.

Power measurements.—The Armington & Sims engine supplying the power worked regularly and satisfactorily and the governor could be adjusted to give the speed required at the dynamo. The Tatham dynamometer was the one used for power measurements at the International Electrical Exhibition, held in Philadelphia, in 1884, where its accuracy was checked by making with it a determination of the mechanical equivalent of heat. The result obtained in the latter measurement was 772.8 foot pounds per degree Fahr., and shows that the dynamometer is practically accurate. A description of the experiments and of the instrument may be found in the report of the test made to the Franklin Institute, but it will not be out of place to briefly describe the apparatus here.

An endless belt, as shown in Fig. 1, passes over the driven pulley, S, to the shaft of which the engine is belted, round the pulleys, S_2 and B, to the driving pulley A, and back over B_1 and S_1 to S, again. The bearings of the pulleys B and B_1 are in cradles pivoted on knife edges, C, at their outer ends, and at the inner ends are connected by links at equal distances on the two sides of a knife edge which supports the scale beam, W. The outer side of the belt passes through the line of the knife edges, C, and therefore has no effect on the scale beam, but the tensions of the inner parts of the belt act directly on the scale beam, and as they are on opposite sides of the fulcrum they act against one another. The beam is so graduated that this difference of tension is read off directly in pounds, and this quantity—the difference of tension of the belt on the two sides of A—multiplied by its circumference and speed, gives the horse-power delivered. A weight travels on the beam, W, and readings can be taken with great accuracy.

Electrical measurements.—The energy in the secondary circuit was measured by means of a Cardew voltmeter and and a Thomson ampere balance. As it is not the custom to put a number of secondaries in parallel, each converter had its separate lamp circuit.

Before making an efficiency test, the potential difference in the primary was regulated,—there being a Cardew voltmeter in that circuit,—and a separate measurement of the potential difference and current in each secondary circuit was made. When the test was actually in progress the voltmeter and ampere balance were used in one of the circuits and the currents and P. D.'s in the others were calculated from the readings in this circuit together with the previous measurements. Both the voltmeter and ampere balance were accurately calibrated, the former being checked after each test, while the latter had its constant determined with both continuous and alternating currents. The P. D. at the terminals of a non-inductive german-silver resistance in circuit with the balance was observed, when a continuous current was flowing, and also with an alternating current of the same period as that employed in the test. The current in each case was calculated from the resistance and P. D., and the results gave no appreciable difference in the constant for continuous and alternating currents.

The following tables show at once the order in which the tests were carried out and the results :—

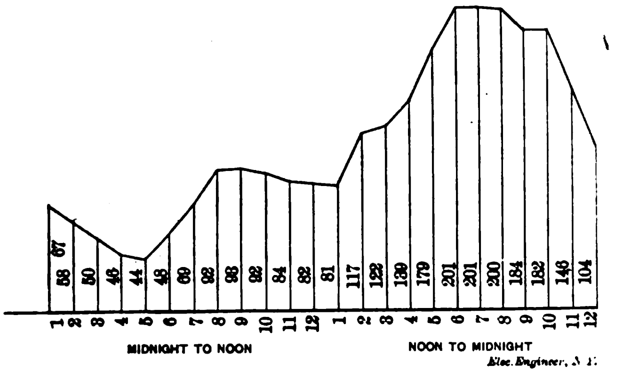
The efficiency of the converters was measured by placing them in a metal calorimeter, between the double walls of which water was allowed to flow. The temperatures of exit and entrance were observed, as well as the weight of water which passed through; at the same time the current and P. D. in the secondary circuit of the converter were measured. A separate observation gave the radiation, which was of course allowed for, although it was made as small as possible. A number of converters were experimented on but I give but two of them; a 40-lighter, such as was used in the tests, and a 20-light converter which was very carefully tested by two of my students, Messrs. Bliss and McKeen. In the latter case the observations were made at slightly different P. D.'s, and the results show that the loss in the iron varies as we would expect it to vary, that is, very nearly as the square of the voltage. The variation will not be exact, as the losses due to the reversal of magnetism do not vary quite as fast as the square of the induction.

I would like here to call attention to the fact that in an excellent paper read before this Institute, Professor Ryan, of Cornell, found that the losses in the iron of a 10-light converter decreased greatly as the load increased. This was accounted for by the fact that there was a jar (evidenced by the singing of the converter) at the higher loads, due to the attractions of the secondary and primary coils. While it is true that the losses in the cores of very small converters are not exactly constant, yet they are nearly so, and a large part of the decrease found by Professor Ryan is due to the voltage being greater at the low than at the high loads.



Elec. Engineer, N. Y.

FIG. 2.

Looking now at the figures given in the tables we are struck by two things; the very large amount of power absorbed in the core of the armature, and the very small loss in the converters on open circuit. The dynamo losses due to reversals of magnetism and eddy currents, at the E. M. F. used in the test are no less than 6 h. p., while the energy due to reversal of magnetism and eddy currents in the 16 converters is only 1.6 h. p. Another rather striking thing is the almost constant ratio of primary and secondary currents over a considerable range. The maximum efficiency is about 78 per cent. It would seem that the losses could be divided into a constant part, and one varying with the current, but this is not true with the older style and smaller converters of the Westinghouse company.

Suppose we have a plant such as is described above, and use it for commercial lighting. Taking data from one of the local companies employed in supplying incandescent lights on this system we have, for two 2,500 light dynamos, the following outfit of converters :—

Size of Converters.	Capacity.			Number in use.	Total Lamps.
No. 1.	5	16 c. p.	lamps.	44	220
No. 2.	10	"	"	61	610
No. 4.	20	"	"	43	860
No. 6.	30	"	"	49	1,470
No. 8.	40	"	"	64	2,560
Total lamp capacity					5,720
Number of lamps supplied					4,557

I understand that the converters being added are of the larger sizes.

The efficiency of the 30-light converters does not differ greatly from that of the 40-lighters. The accompanying Fig. 2, is a load diagram of this plant, selected from a number of diagrams as giving a fair average curve. If we have our dynamo working to its full capacity then from the above data we would have a converter capacity of twenty-three 40-light converters.

If, as in our test plant, these converters are 40-lighters, or 30-lighters—for the efficiency of these two sizes is about the same,—we would have a mean loss in our plant of, say, 10 h. p. in our dynamos ($9.6 + C^2 R$), and in the converters about 3 h. p. ($2.3 + C^2 R$); or all together about 13 h. p. From the above table we will have 750 lamps supplied, and taking the data from the load curve the average load would be in the neighborhood of 1,300. This corresponds to about 20 h. p., and the efficiency of the plant for 24 hours would be $\frac{20}{33} = 61$ per cent., minus the percentage of loss on the lines. This, in a properly installed system, should not average two per cent., so that the final efficiency would be 59 per cent.

A continuous current dynamo supplying the same outfit of lamps, with a maximum loss in the mains of, say, 15 per cent., would have a greater average efficiency. But I wish to point out that the maximum efficiency of the two plants would be about the same, so that they would require the same capacity of station outfit, boilers, engines, dynamos, etc. When more than one dynamo is provided the efficiency is increased by using only one of them during the times of minimum supply, and always working as far as possible only a little below the maximum capacity of the machines.

Let us consider these results in view of the present condition of incandescent light distribution in the United States. I take it that what may be called domestic electric lighting is largely a matter of the future—it is certainly not a matter of the present. The majority—the great majority—of the lights in use are in shops, saloons, theatres, offices, etc. Most of the lights wired are in use at one time or another during the 24 hours, and the proportion of energy supplied to the total capacity of the lamps connected is much greater than it would be in the case of house lighting, where, on the average, only a small fraction of the possible lamp-hours are actually in use. Under these circumstances the scheme of alternate current distribution is very different from what it will be when the attempt is made to supply an entire city with light, as they are attempting to supply London at the present time.

If the object of the lighting company is to supply the demand that exists at present, then a system employing a number of small converters is preferable. Such a system is flexible and can be installed with a minimum expense for the more or less scattered demand which is presented in even the most closely settled town. I take it that this is the great difference between the alternating and direct systems as at present installed in this country. The former skims over an extended district, taking advantage of its great flexibility to absorb any business which can be got; while the latter settles itself in a densely built centre, installs a larger plant than is primarily demanded, and works up a business within the limits of economical distribution. Therefore, it is hardly right to compare the present systems of direct and alternating supply, as the latter has not been reduced to a point where entire districts are to be supplied.

To show the disadvantage of the present system for domestic supply, suppose we have an ordinary house such as one of us would live in; it would be necessary to have a converter of at least 20-light capacity. The constant loss is, say, 100 watts; so, leaving out the $C^2 R$ loss, we would have a total loss in 24 hours, of $\frac{2400}{750}$, or about 3 h. p. hours, corresponding to, say, 45 lamp hours. Taking my own experience the actual number of lamp hours used is about 30 lamp hours during 24 hours, so the efficiency of the converter would be something like $\frac{30}{75} = 40$ per cent. It is evident that unless the losses in converters can be greatly decreased, a house-to-house distribution with a converter in each house would hardly pay.

It would seem, then, that if gas is to be really displaced and serious competition with it is to be attempted a different system of distribution must be worked out. We must replace the numerous small converters with one large converter supplying a comparatively extended district, thus decreasing the converter capacity, since the law of average can be taken advantage of, and greatly increasing the efficiency. If an extended secondary network is employed, some of the converters may be disconnected from the mains at the turn of minimum demand.

Let us inquire for a moment how the increase in the capacity of converters will modify the designs with which we are familiar. In the first place, if we increase the linear dimensions of any type, since the radiating surface only increases as the square while the volume increases as the cube of the dimension, then we cannot suffer the same loss per cubic centimeter of the iron for the large as for the small sizes. We must decrease the intensity of magnetization or we must decrease the periodicity.

Let us take a typical case. Suppose we have a transformer and double all of its dimensions. If we employ the same induction we will need but one quarter the number of turns in the coils, and as the cross-section of the space occupied by the wire is four times as great, the area of the wire may be sixteen times as much. As the length is twice as great, the resistance in this case is one-eighth. But the losses in the iron are, roughly, eight times as great; this we cannot allow, since the radiating surface is but four times as great; hence we must diminish the induction. In fact we must so arrange things that the loss in the larger converter is only four times that in the smaller, in order to work at the same temperature. As at the low induction used the loss due to hysteresis varies nearly as the square of the induction we may take it roughly that the large converter should have an induction of three-quarters of the smaller one. This will modify our figures. Instead of one-quarter the number of turns we will have one-third, and the resistance of the coils will be one-sixth instead of one-eighth, as we can allow four times the loss that we suffered before, we can have, roughly, five times the output.

As a total result we have five times the output with four times the loss, or, as the $C^2 R$ effect is not important as compared with the other losses, we can have six times the output with the same fall of potential in the secondary. That is, the efficiency of the larger converters will be greater than the smaller ones of the same design and working at the same temperature, but the output per pound of metal will be less.

Suppose when we increase the size we decrease the number of reversals. Take a case, for instance, in which the dimensions are doubled while the reversals are halved, the maximum induction remaining the same. We could have half the turns in the coils, and as they occupy four times the space and are twice as long the total resistance would be one-quarter, and for the same heating effect we would have four times the output.

If we take losses by eddy currents into account there will be a constant per cubic centimeter, provided the period and maximum induction are constant and the thickness of the plates is unchanged; otherwise they will vary as the square of the induction, with a constant frequency, or inversely as the square of the period with a constant maximum induction. This in practice would make the values of the output for the larger currents given above somewhat greater. What I wish to show, however, is that we are limited by heating considerations and considerations of fall of potential in our secondary in the output of large converters. If we consider the properties of the materials of which converters are made we would, I think, find it most economical to make converters that reach the temperature limit, except for the very smallest sizes.

Many of us have, I suppose, read Mr. James Swinburne's paper read before the British Association at Newcastle last year on the "Design of Converters," and have been struck by the fact that almost all of the converter dimensions given by him are impracticable, either on account of the disproportionate heating of the larger sizes, or the excessive fall of potential in the secondary. In increasing the size of dynamos we usually increase the output per pound weight, but there is the vital distinction between dynamos and converters that losses occur through the entire mass of the latter, and as we increase the volume we increase the losses in the same proportion. In the dynamo, on the contrary, there are practically no losses in the heaviest part of the apparatus, *i. e.*, the field magnets. As a result, while we gain in efficiency in the larger sizes, yet we must decrease either our induction or the rate of reversal, and the output per pound is not increased.

It has learned that to a true union of science with art only, are we to look for the methods and the means by which mankind is to be finally, if at all, emancipated from the yoke of overburdening labor now so terribly oppressing the race.—*Professor Robert H. Thurston.*

DATA AND PLOTS OF VARIOUS INCANDESCENT LAMPS TOGETHER WITH AN IMPROVED METHOD OF TESTING.

II.

BY WM. L. PUFFER.

From Graduation Thesis on the Distribution of Light Around Incandescent Lamps, with Efficiency Measurements. By Henry M. Hobart and Earl W. Gannett, Massachusetts Institute of Technology.[1]

The object of this investigation was to determine the efficiencies of various makes of incandescent lamps. The method used was similar to, but in all respects an improvement upon, that used in 1885, by the Franklin Institute. The component measurements to be made are these :—

1. The current passing through the lamp.
2. The difference of potential between the lamp terminals.
3. The required photometer readings.

The current was determined by a Thomson current galvanometer placed in series with the lamp and an adjustable resistance for regulating the potential. The difference of potential was determined by a Thomson potential galvanometer of 7,500 ohms resistance connected to the terminals of the lamp. Great constancy of potential was rendered possible by the use of an automatic governor designed and built by the department. The current readings were corrected by deducting the current flowing through the potential galvanometer.

(The description of holder and method of working are omitted as they are similar to those given in first part of the paper.—W. L. P.)

The following varieties of lamps were tested in the order given :—

Lamps C, D, M,	Sawyer-Man,	110 volts,	16 c. p.,	marked 16 c. p.,	A 3-16 c. p.,	A 4
" A, B, L,	"	60 "	16 "	" 16 "	B 4	
" I, J, K,	Weston,	110 "	16 "	" 16 "	110 volts, B.B.G.	
" E, F, N,	Edison,	110 "	16 "	"	Edison's patents, 16 c., 3.1	
" R, S, T,	"	93 "	16 "	"	" " 16 c.	
" O, P, Q,	"	85 "	16 "	"	" " 16 c.	
" G, H,	"	110 "	32 "	"	" " 32 c., 3.1	

Three separate lamps of each kind were tested ; two separate tests by different observers were made on each lamp and their means taken to represent the values for that particular type of lamp.

Therefore, 42 tests were made on 21 lamps of seven varieties. Every final result is the mean of the results for three separate lamps and for six separate tests. Every point plotted on the diagrams is the mean of 24 settings of the photometer disc. Four careful determinations of the value of "H" were made by the Kew magnetometer, at the outset. The four results and their mean are .1747 — .1751 — .1744 — .1748. Mean = .1748.

The accuracy of the results was ensured by checking at three different stages of the work, the means of the results and the results of the means.

Photometric observations on lamp J, being a mean of observations J, by E. W. G. and J_1, by H. M. H.

The accompanying two tables are taken from the thesis to show methods of combining results and the agreements.

In addition to these results it is necessary to know three more things before deciding which lamp is the best one and the cheapest to use :—1, cost of new lamps ; 2, life of lamp when burned at proper voltage ; 3, fall of candle-power due to increase in the life of lamp.

Under the cost of lamps must be reckoned the percentage of broken lamps which are always found in a batch of new lamps, the number which break instantly or within a

few minutes of the time the current is first turned on; those with defective fittings or otherwise in such condition that they cannot be burned. What experience I have had with lamps of the above kinds points to the conclusion that from three to five per cent. is about the proportion of loss; from actual count on one of the makes I find that I lose about five per cent. of every new lot. This loss makes a very material difference in the cost of a lamp and must be taken into account. As to the life of lamp and fall of candle-power with age, I have no figures ready for publication. It is a very open question whether a lamp's life ends when it ceases to give say 50 per cent. of its original light or when it becomes blackened, or when the filament actually breaks. From the moment the current is first turned on the lamp begins to depreciate, sometimes increasing and sometimes diminishing in candle-power, or even both, until the filament finally breaks. I believe in a lamp that maintains its original light, or possibly increases it, until it has run a number of hours and then fails rapidly and breaks, and not in a lamp which is at rated candle-power only for the first few hours of its life and then dies by slow consumption at the end of its guaranteed life with a light only perhaps five or ten per cent. of its original brightness, having lived as a "red-hot hair-pin" for the last half of its life.

It should be stated that all of the Weston and Sawyer-Man lamps were bought in Boston of the supply companies out of stock, and were in their original wrappers when taken for test. No questions were asked as to the use to which the lamps were to be put. Of the Edison lamps tested, the 110 volt 16 c. p. lamps came out of a stock of lamps on hand for general lighting use, but the rest were ordered by the local Edison company from the lamp factory, knowing that they were for testing purposes. Lamps could not be bought without a declaration of the purpose for which they were wanted.

DR. LOUIS BELL ON LONG-DISTANCE ELECTRIC TRACTION.

At the meeting of the Chicago Club, March 17th, a paper written by Dr. Louis Bell on "Electric Motors for General Railroad Work" was read and discussed. Like Lieutenant F. J. Sprague, the author of the paper, looks confidently for the operation of electrical trains at railroad speed. He thought that it was practical to build motors sufficiently large and reliable to equip trains to run on through lines. The problem of transmitting power could be solved by dividing the road into sections, by locating a power station in the centre of each division. At the present time he did not think such a plan would be much more economical than the method of using locomotives unless a saving could be effected by better firing and by using a cheaper grade of coal, and by operating motors lighter than the engines now employed in drawing trains. It would be possible to make the motor lighter, he thought, because the electric current transmitted to the rails gave an increased traction. In the case of suburban roads and of short lines between neighboring cities, he thought the substitution of electric motors for locomotives would result in a substantial reduction of expenditure. The electric motor, he thought, was especially adapted for use on elevated railways, and he could see no reason for the continued employment of engines for drawing trains when the electric system on such a road was so incomparably superior.

.... THE existence of an ether can legitimately be denied in the same terms as the existence of matter can be denied, but only so.—*Oliver J. Lodge.*

.... IF one electric light company purchases its fuel for 50 cents per ton and another pays $3, the results will soon show in the profits.—*A. F. Upton.*

THE SHAVER MOLECULAR TELEPHONE.

There are many situations in which telephonic communication is of importance but in which the expense involved in the operation of the electric telephone does not warrant its introduction, and some form of mechanical telephone, therefore, becomes desirable.

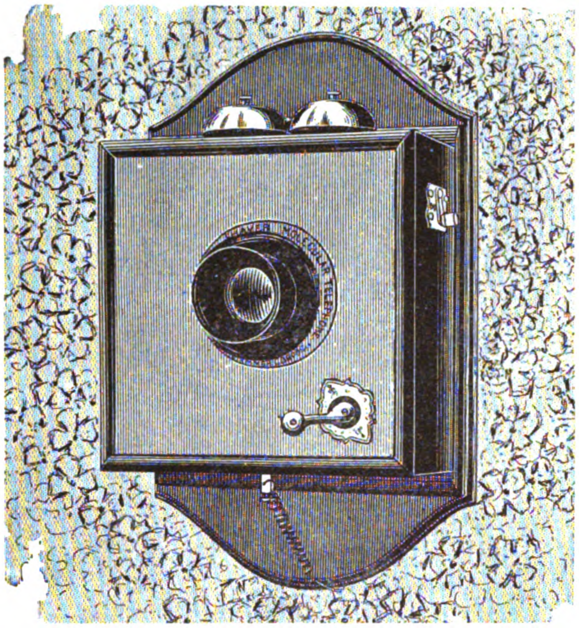

Fig. 1.

Mr. George Frederick Shaver, who has long made the subject of mechanical telephones a matter of study, and is well known as a fertile inventor, has recently brought out an improved form of apparatus known as the "molecular telephone." The principle upon which this telephone is based may be said to be an extension of the well-known phenomenon observed in the transmission of sound through a log of wood, in virtue of which the scratching of a pin at one end may be heard by placing the ear to the other end. Applying this principle to the mechanical telephone, Mr. Shaver employs a peculiarly-formed resonator, which is bell-shaped, and to the centre of which a cable wire of peculiar construction, forming the line, is attached. The outer lip of the bell is held in a vulcanite frame combined with a sounding board, which is so sensitive that by breathing against one of the diaphragms the sound is reproduced at the other end of a line two miles in length.

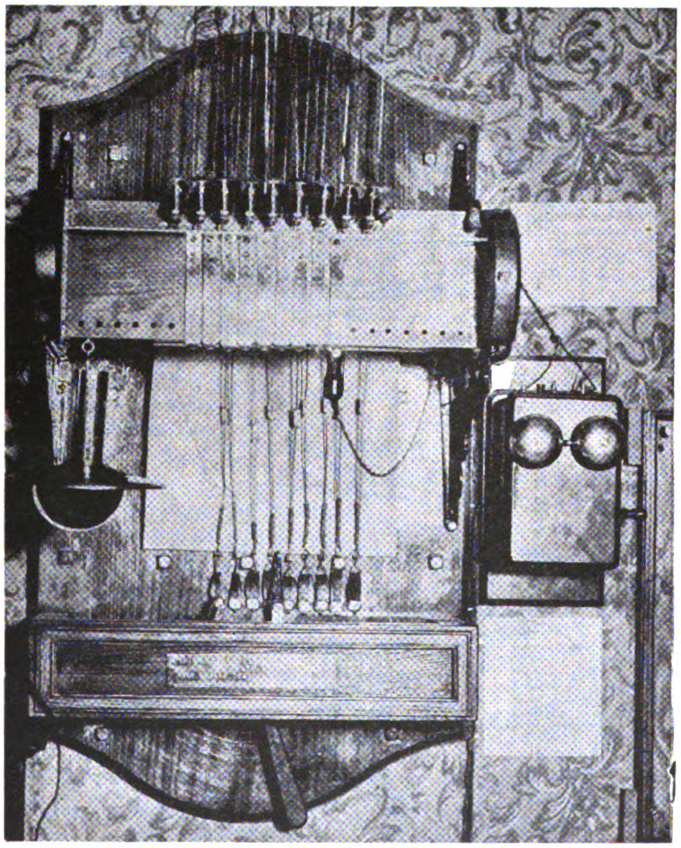

Fig. 3.

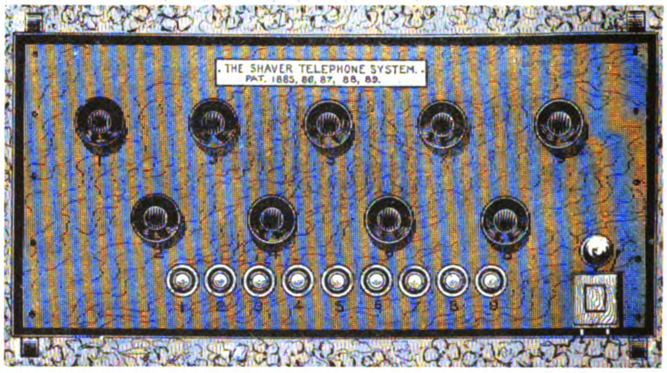

THE SHAVER TELEPHONE SYSTEM.
PAT. 1885, 86, 87, 88, 89.

Fig. 2.

The accompanying illustration, Fig. 1, shows the regular instrument for a single line. It is used both as receiver and transmitter, and is provided with the Gillette magneto call; and these single instruments are well adapted for private lines, and operate nicely through distances of two miles.

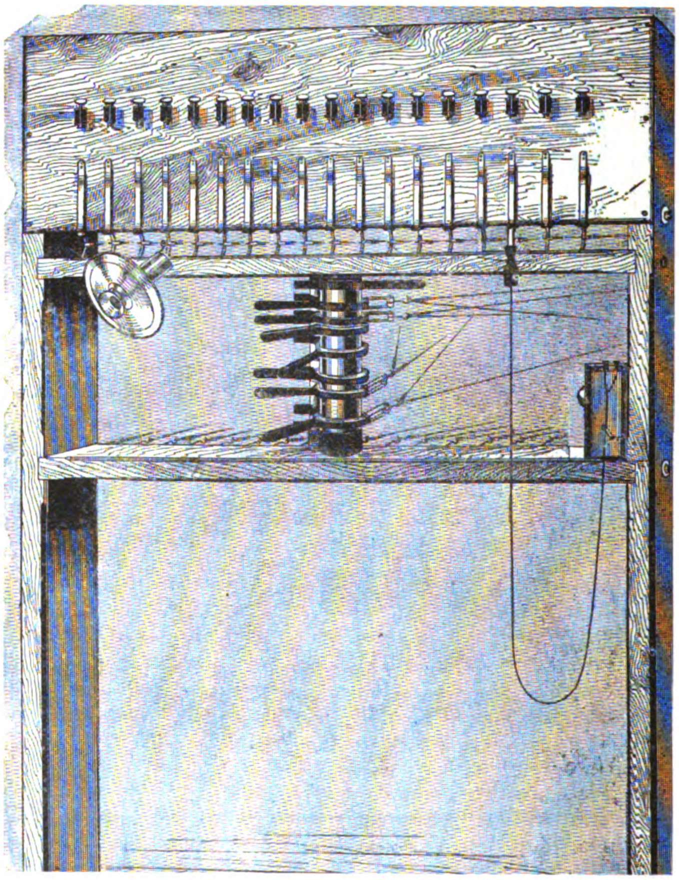

Fig. 4.

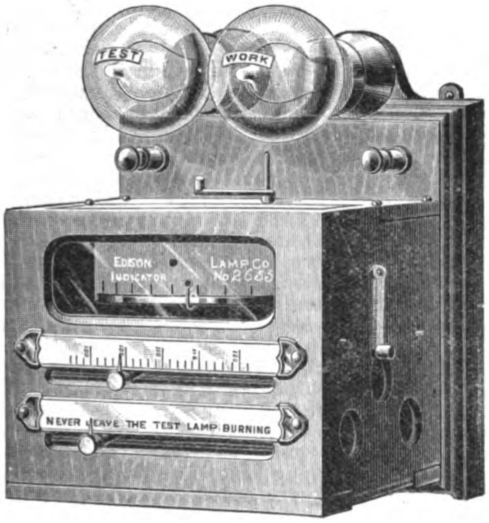
The system is also well adapted for club lines and requires no attendant, each station being able to call up any other station upon the circuit direct. For factory use, one of the arrangements employed is that shown in Fig. 2, which is specially suited to communication between the office of a factory and the various departments. Another form of this apparatus is shown in the engraving, Fig. 3, which represents a telephone exchange system with a switch for connecting different stations together and is specially adapted for inside work.

The system has also been very completely worked out for general exchange work where the number of subscribers does not exceed 100, and is effective within a radius of one-half mile about the station, allowing a mile distance between subscribers. Such an exchange is shown in Fig. 4, and of course requires an attendant to do the switching to connect the subscribers, as in the service now in vogue in the electric telephone exchanges.

We may add that this type of telephone has been adopted by the Lehigh Valley, Delaware, Lackawanna & Western, New York Central and a number of other railroads, and that it has been also approved by the Government for some of its work. The articulation, which we have had occasion to test more than once, is quite clear, the sibilants especially coming out very distinctly. The instrument is manufactured by the Shaver Corporation of this city.

NEW EDISON TWO-LAMP PRESSURE INDICATOR.

Our readers are without doubt generally familiar with the pressure indicators used in connection with Edison isolated plants. These instruments embody in their construction the Poggendorff method of measuring potentials, and one of the resistances employed consists of an incandescent lamp which is constantly in circuit. Experience has shown, however, that the carbon filament in the lamp on the one-lamp pressure indicator changed in time so that it became necessary to recalibrate the indicator in order to maintain correct indications. Hence it was desirable to add to the instrument a means by which the egineer operating the plant could quickly and easily restandardize his instrument.



Edison Two-Lamp Pressure Indicator.

This improvement virtually consists in connecting two indicators through a switch to the same points in a circuit, using one lamp as a working indicator to be kept constantly in circuit, while the other is kept out of use until such time as it is thought necessary to throw it in, in order to check the other. This is done in one instrument by putting on two lamps and two sliding resistances and so connecting them with a switch that when one lamp is lighted one slider is used, and when the other lamp is on the other slider is in use.

In the two-lamp pressure indicator, which is shown in the accompanying engraving, and is manufactured by the Edison Lamp Co., the "Test" lamp is the one which is kept for a check while the "Work" lamp is always in circuit. By this arrangement the engineer in charge of a plant can at any time test the accuracy of his instrument and thus avoid excessive lamp breakage due to the carrying of too high a pressure.

SENDING PICTURES BY TELEGRAPH.

Among the large number of methods of transmitting intelligence the fac-simile has always had a charm for inventors, and the transmission of sketches and diagrams has been accomplished in a variety of ways. Recently Mr. H. Rickinson, of Islington, London, has brought out a method which is based on a principle which has already been applied, but which is carried out to a somewhat minuter degree than heretofore. In this system the original sketch is divided up into squares by means of ordinates and abscissæ, and each square is identified by the letters which are ranged along the sides of the chart. Each of these squares is again divided into five parts, which are identified by the numbers 1, 2, 3, 4 and 5, and each such part is divided into two, and half the part is denoted by the letter *j*. Any point in the picture thus has two co-ordinates, as in analytical geometry, and these co-ordinates are communicated by telegraph. A broken line is, of course, identified by a number of points taken along it. When the sketch has been reproduced by joining the points constituting the lines, the details may be filled in by the aid of the descriptive words added.

THE GANZ ALTERNATING CURRENT MOTOR.

The city of Frankfort-on-the-Main decided during the past year to inquire into the various methods of electric distribution, with an ultimate view to the adoption of the one best suited to its wants. To arrive at a proper conclusion the town council placed the matter in the hands of a committee consisting of some of the most prominent electricians in Europe, whose report has lately been rendered. During their investigations the committee had occasion to test the new Ganz alternating current motor, and the results obtained are interesting in several respects.

On the question of the output and efficiency of the Ganz motor, the committee report that experiments were made with the 25 h. p. and 5 h. p. types. The former gave efficiencies of 82 per cent. to 88 per cent. for outputs of 15 to 35 h. p.; the 5 h. p. showed efficiencies of 60 per cent. to 80 per cent. for outputs of 3 to 8 h. p., the figure for normal load being on an average 78 per cent. The efficiency, therefore, does not differ to any important extent from that of direct current motors.

With respect to starting, it was found that the 25 h. p. motor could not start itself, and the smaller sizes, 5 h. p. and ½ h. p. were unable to do so in certain positions. A test as to starting the motor with full load on was not made, as Messrs. Ganz & Co. objected to it. The time necessary for the attainment of normal speed was from 30 to 45 seconds. The start was always accompanied by heavy sparking at the brushes, diminishing as the normal speed was reached. In the 25 h. p. machine these sparks were 5 cm. long, and 3 cm. on the 5 h. p. machine. At normal speed the sparking was not worse than with direct-current motors.

With regard to noise, the committee pointed out that from the nature of the action, as well as from the sparking, when not running synchronously, more noise was to be expected from the alternating current machine. In factories and on tram-cars this noise was unimportant; but it would exclude the larger sizes of the motor from dwelling houses, unless exceptionally good foundations were secured. With the small motors the noise would not exceed that of the machines used to drive sewing machines with. The motors being synchronous, regulation of speed could only be arrived at by means of multiple-speeded pulleys.

A series of tests was made to ascertain the effect of sudden application of load and of overloading, and it was found that the 25 h. p. motor did not fall out of synchronism till it was loaded with 40 h. p., and the 5 h. p. motor could be loaded up to 8 h. p., in each case a maximum load 60 per cent. in excess of the normal. A sudden load of 26 h. p. can be put on to the large machine when running light, though a heavier load than this suddenly applied will cause it to stop. When running at 26 h. p. a further sudden load of 8 h. p., and after the application of this a further 6 h. p. can be put on, the total load being then 40 h. p. The whole of this load can be suddenly removed without affecting the behavior of the machines. The 5 h. p. machine could take a sudden load of 6 h. p., which in the same way could be suddenly increased to 8. It should be mentioned that the machines tested were the second of their respective classes that had ever been built.

. . . The only money to be made in the future in electric lighting under the coming competition is to be made in saving.—*A. F. Upton.*

. . . . In the past the arts have led; in the future we shall see science leading and directing every development of the arts.—*Professor Robert H. Thurston.*

THE SOCIAL SIDE OF THE ELECTRIC RAILWAY.[1]

BY T. C. MARTIN.

A MONTH or two ago we had the pleasure of listening in this hall to a most interesting paper by Mr. S. Dana Greene on the development of electric traction. I had previously promised the secretary of the society a paper on the same subject, but I felt it would be useless for me to traverse the same ground again. Mr. Greene spoke with authority, and not as one of the newspaper scribes; and I was glad to learn from him and accept most of his conclusions. I recognize the fact, however, that he dealt with the topic mainly on its technical side, as a specialist of experience, and that there was still a very important branch of the subject on which a few helpful words might be said—namely, the relation of the electric railway to the public and to social conditions generally.

Few of us stop to think of the enormous difference that facilities for travel make in our lives. I do not refer to the opportunities and appliances for long journeys, but to the simple everyday transportation that we calmly accept as a prime condition of existence. It is probably safe to say that every one of us came here to-night, and will go home, without depending on our legs to make the trip. But this is altogether modern, and to the generation immediately preceding ours would have seemed as unlikely as that, from total lack of exercise our legs should become atrophied and own no function of pedestrianism. Yet now that we have enjoyed the advantages that the means of artificial locomotion already familiar give us, we want more. The Harlemite does not consider it rapid transit unless he goes from City Hall square to the rocks and goats above Mount Morris park in an hour and a half, and his discontent with the steam railway on stilts becomes daily diviner and deeper. The citizen of Brooklyn is not satisfied to be reduced to a despairing calculation as to whether he is after all better off by being jammed and gouged on the bridge than by balancing on one trodden toe upon the old ferry boats, before he can reach his little vine-clad, mortgaged home at the back of the east wind. And as for the Jerseyman, it is needless to say that of all the ills of his wearisome daily travel, he is able to commute only one. Still, we are infinitely better off in choice of location for our homes than were the people of Manhattan before us, who knew not the elevated railroad, and never gladdened their eyes with the majestic spectacle of the platform of Brooklyn Bridge at a quarter to six on a wet March night, with the cable broken down. If you will take the trouble to invite the candid opinion of the "oldest inhabitant" as to the vanished Broadway stages, the early street cars, and the ancient ferries, you will learn that we have scored a distinct advance. That is why we all want something better.

This is a barbarous age we live in, but we have a foretaste of the civilization that awaits our descendants. We are beginning to learn that luxury is a relative term. A hundred or even 50 years ago there was no such thing as luxurious travel. Washington came to New York to be installed as president, in a manner that a fastidious drummer might now despise. De Quincey was willing to give five years of his life for an outside place on a stage coach that carried down from London through the English counties the news of a great event. We save our five years and our health, and get all the thrill we want, by blocking up the sidewalk on Park Row, and reading the newspaper bulletins as they cover one another on the boards, like successive waves of emotion, rolling in from the unseen but tangible, throbbing distance. We know what the past was. The blizzard of two years ago brought us down to the normal, average conditions of semi-savagery in locomotion as it prevailed prior to the introduction of the steam road, conditions that need all the glamor of the romancist to be made even tolerable as a picture to the New Yorker who boards the Pullman special for the south, and has had his pleasure in Florida, and returned before the storm that was in progress when he left has gone eastward to discover Europe.

What steam has been to long-distance travel in replacing the stage coach and the sail, electricity is in turn to urban travel in replacing the horse car and the cable road. Later in this paper I will indicate the manner in which electricity may sooner or later realize the best and brightest promises made on behalf of the trans-continental steam railroad, but our first thought is as to electrical travel within towns and cities, and the manner in which it affects social relations, by modifying as with the harlequin wand of transformation all the conditions to which we have heretofore been subjected.

In speaking of this great advance in electricity as applied to the comfort and convenience of man, I do not wish to be understood as praising a perfect thing. We are in the early stages of practical electric locomotion. The pioneer work has been done by young men, still among us, much too near their salad days to fall into the reminiscent vein. It is barely three years ago that I had myself the honor of bringing before the American Institute of Electrical Engineers the first statistics published on American electrical railways, when I seized with brazen audacity upon every bit of a track that could possibly bear inclusion as a road. I would be understood rather as appearing in advocacy of an improvement in many respects crude, but that is not yet appreciated even as it stands. We of the electrical industry have a great duty in this respect, of preaching the advantages of electric locomotion, in season and out of season; and by our persistency we can help the art along. The phrase that good wine needs no bush was not coined by an American advertiser, and the idea that electricity will make its own way is not justified by the history of any great invention that has yet subserved the needs of mankind. Electric locomotion is, however, ready for adoption at an opportune moment. It offers itself at a time when every thing else that has been tried for urban travel, has revealed objections and disadvantages, the more keenly realized because of our higher conceptions of what such travel may be. It is a singular principle that as a system or device reaches perfection something comes forward to supersede it. The horse coach was at its height of speed and comfort when the steam engine challenged it. The white-sailed China clipper was never swifter than when it lowered its flag to the conquering steamship. And so to-day, the horse, the cable and the steam locomotive have shown the utmost that they can do, just as the electric motor rolls to the front and takes the stage, as the means best suited to the peculiar requirements of passenger traffic in modern towns and cities. I do not say that it will banish these competitors from the scene, but I do maintain that its superiority will quickly gain it the decided preference. I am always suspicious of an invention or improvement that is going to knock out everything else, like a charge of dynamite. History is against any such phenomenon. What we do see is a limitation of the antecedent methods and appliances to the sphere within which they are most useful and economical. The old is restricted to its proper place and function as by a ring of fire; the new goes on making its own kingdom until at last its boundaries of achievement are also determined. Thus, as Tennyson puts it, "God fulfils himself in many ways, lest one good custom should corrupt the world."

The first of the social considerations to which I would direct notice is the effect on the public of the adoption of electricity as a motive power for street railways. The struggle for supremacy in urban passenger work has already narrowed down strictly to the horse, the cable and the electric motor. As everybody knows, steam motors are completely out of favor for use within city limits. Their glorious record of half a century in long-distance travel does not deceive anyone dwelling in a city as to the insuperable defects and nuisances of noise, smell, smoke, dust, steam escape, oil drippings, etc., which may more readily be tolerated, remotely, in the open country. Perhaps I am wrong, but I believe we shall not see any more steam roads in New York, and that imposing as are the statistics of the Manhattan elevated system to-day, they will be eclipsed in a very few years by those of the newer form of electric locomotion. And may not the same be said as to the horse? There are now close upon 15,000 horses engaged in hauling street cars around this city. It is high time that every one of these was dispensed with, as well for its own sake as for that of the city, whose air it assists in polluting and whose population it aids in driving into exile. Allowing an average space of 40 square feet to each horse, or a stall 9 feet by 4½ feet, we find that in stall space alone those 15,000 horses occupy 600,000 square feet of floor in their stables. These horses are required to operate some 2,400 cars, an average of about seven to the car if every car were in commission at once, which is not at all the case. But even if nearly all the cars were wanted, an average of 10 h. p. each would be ample in the central station of an electrical plant, bringing us to a liberal allowance of 25,000 h. p. But here comes in the remarkable though not unfamiliar fact that a steam plant will go into much less space than an animal power plant of equal capacity. Mr. C. J. Field, who is known to many of you as a constructing and mechanical engineer, informs me that his recent practice shows that a generating electrical plant for 20,000 h. p., to operate all the street cars of this city, could easily be placed in a building 100 x 150. The engines and the dynamos would be placed on the first floor, and the boilers on the second floor. The generators in such a plant would be multipolar, 500 h. p. each, directly connected to the engines, and each engine would be of a vertical triple expansion type, of 500 h. p. each. This gives only 1½ square feet to the horse-power, and we may offset the space for feed, etc., by that for coal, etc. I have tested these figures by those of recent electric light stations in actual operation, and they are found to be very fair and reasonable. It might be objected that all the power would not be bunched in this way; but even with half a dozen generating stations of 2,000 h. p. there would only be an increase in space required of about ten per cent. From this remarkable but strictly proper comparison, we can form an idea as to the economy of real estate, bearing in mind also the fact that horse car stables are generally wooden or brick sheds, only one or two stories in height, while an electrical plant may be run up as high as an apartment house or an office building, just as ornate without, just as clean within.

Hence there can be no mistake in the statement that electricity is a direct boon to the urban population that clings to the city, loves the city life, and that if crowded out from it into the country suffers all the pangs of banishment. Indirectly, too, it is a further boon because with horses a great portion of the district surrounding the car stables is also spoiled for human habitation. The whole region within what I would define as "the area of smell" is unsavory and unhealthy the year through, and the consequence is that while the taxing and renting value of it is lessened, the death rate is run up. "Do not insult a respectable animal who has come from the country to do his share of the work of the world," says one authority, "and has brought with him the memory of the sweet hills and skies at least, by immuring him in one of those cramped, rickety, rotten, slovenly, damp dungeons, where a dumb beast would lose his self-respect and his courage, beneath an oppressive weight of miasma, and hideous, gloomy, nasty confusion." And so say all of us, and all of us are glad to note a vast improvement in this respect. The stables are better ventilated now as a rule, but the trouble is just there. If they were not so well ventilated, the neighborhood would be sweeter, and would be fitter for human beings to live in. The poor die quicker that the horses may suffer longer.

---

[1] A paper read before the New York Electrical Society, March 12, 1890.

An objection I may anticipate is that, after all, such large generating plants would not be desirable with their huge smoke stacks, their discharge of gases, etc., upon the atmosphere, their receipt of coal and their removal of ashes. I would reply that it is by no means necessary for such plants to be, as the stables must be, right upon the main lines of travel. They would by decided preference be located near the water's edge, out of the way. Moreover, the stacks would be, as they are to-day in large electric light plants, high enough to carry off all smoke or smell far beyond perception. Perhaps the familiar smoke stack is not an æsthetic object, but it can be made so. There are steeples in this town that on the score of their beauty are not fit to compare with smoke stacks near them.

Much that I have said under this head with respect to electricity applies to the cable. That system has been an immense advance in street car travel, and is destined to many years of usefulness yet. It is worthy of much praise; but it will not hold its own with electricity, simply because it is deficient in some things that electricity possesses to a pre eminent degree. It has been a forerunner for electricity. It is not only enormously costly in its first installation, but has the disadvantage of being a unit. The whole of the road and all its power hangs by that one cable. If the cable be duplicated in the conduit, the expense is again so much the heavier, while the criticism as to risk still stands. Moreover, a cable car cannot go backward at its driver's will. Onward it must go, Mazeppa-like, strapped down to its carrier, no matter what unfortunate contingency impend, or what obstacle lies in its path. It cannot greatly vary its own speed. An electric car is so manageable that it will reverse in its own length or less. But the greatest trouble of all with the cable is that it is always the one thing, while there are very few towns or cities that are alike in offering just the rigid Procrustean conditions it meets. There are about 50 cities in the United States with a population of over 50,000, but there are between 700 and 800 street railway companies, if not more; so that even if all the places in the first category could justify the heavy expenditure on a cable system, there are hundreds of others unable to do so. We need not wonder then that at their last convention in Minneapolis, the street railway men gave electricity such a hearty welcome, adopting the enthusiastic if not elegant language of a committee report which said that it "filled the bill to perfection." Nor need we wonder that the street railway company in Minneapolis has just thrown aside an unused cable plant that cost $400,000, and is putting in electric cars and over 100 miles of electric road.

Why does electricity "fill the bill," and in a manner that interests the public? Well, for the reasons given already and for others. It is above all things flexible, plastic, protean. It can be applied in half a dozen different ways, and be absolutely safe for human life in any and all of them. The street railway may be equipped with an overhead system for supplying the current to the motors, and to that system, well built, with trim ornamental poles, lines well run and guarded, little or no objection can be offered. The air is God's own insulation; we know none better, none so cheap, and a wire is well insulated up aloft. The Bostonians, who are people setting no small store by their refined, acute and cultivated taste, have adopted poles and wires in preference to the hideously ugly lattice work tunnels we have in New York to hold up our elevated roads, and I admire them for it. It is possible that Boston may have an elevated road, but if so it will be a handsome electric one. Or, if the overhead wire be objected to, as it may, there is the conduit system, which is fully able to give a good account of itself if well put in and plenty of money be spent on it. It is true that the wires are not exposed in the conduit system, but otherwise there is not much operative difference between it and the overhead method. There may be difficulties in heavy wet, or snowy weather, but we shall see them all overcome. Or should this or its modifications again be found fault with, there is the ideal storage battery system, where each car starts out "on its own hook," an independent, self-contained unit. I don't exactly know why we call it the "ideal system." It is either within reach or beyond. If within reach, it is not "ideal," but ought, speaking from the public standpoint, to be adopted wherever there is actual need for it. It may be a trifle expensive, but that is certainly not one reason more why the public should do without it. It may be somewhat difficult to put and keep in order. "Coaches, Sammy," said the elder Weller, sententiously, to his son, "coaches is like guns—they require to be loaded with werry great care afore they go off," and that is about the case with the storage battery cars. But they do go off, and we know from the approval they have met with that they do hit the mark of popular approval,—and that is one of the main things I am talking about to-night.

It is in one or other of these systems or modifications of them that electricity will become familiar to the public of this country in street railway work. It will, I think, be chiefly for a long time to come, the overhead system, which is not costly to put up, is not expensive to maintain, can be operated economically at about half the running charges of animal power, and fully answers the requirements of the vast majority of our thriving, intelligent centres of trade and manufacture. All these methods are safe, and none of us ever heard, or expects to hear, that the current of 500 volts they have employed has taken a single human life. The motor cars cannot "explode," the daily papers to the contrary notwithstanding. They scatter no dust or ashes; they do not litter the streets with offensive refuse, but rather ozonize the air; they are pleasant to ride in and they do not damage the paving. They require good tracks for their best operation, and naturally make their worst showing on the automatic mud sprinklers that so begutter the roadways in this city. But the roadbed between the tracks they never touch. It might as well be a continuous plot of flowers. In the outskirts of Boston, some of the electric cars whose aerial wires run hidden between the overarching trees, have their tracks laid down on a narrow green lawn for three or four miles; and at a remove of but a few feet, it seems to the spectator as though the cars were gracefully skimming over the smooth grass, in effortless flight, like low-darting, even-poised swallows.

I have just spoken of the outskirts of Boston, and this brings me to another important point wherein electric cars are an element making for the public good. They help a man to get farther away from his business, and yet bring him nearer to it. "Rapid transit" by their means is no longer a deceiving phrase, or the proud monopoly of one or two big cities. The smallest city in the country is at once given a command it never had before over the territory around it. The smallest store keeper or the humblest clerk can revel in the sweets of rural life, if he wish. His electric car, running at 15 or 20 miles an hour, will give him more of home life—a few golden minutes with the children in the morning, an earlier return to the wife at nightfall. The whole social atmosphere of the place is vivified, and the social bonds are knit closer, as they always must inevitably be where the facilities of travel are increased, and the opportunities of intercourse are multiplied.

Nor is this all. Rapid transit of this nature opens up a number of districts that before were practically inaccessible for residential purposes. There are few of us who care to practice the ancient form of dissipation known as early rising, agreeing rather with Charles Lamb, in the idea that to rise with the lark or go to bed with the sheep is a popular fallacy. There are still fewer of us, who, even for the sake of rural delights, care to isolate and immure ourselves in remote suburbs reached with difficulty. In vacation time, it is true, we often seek the loneliness of the woods, or the solitude of the mountains, that we may commune with Nature and hear the still small voice of our better self; but when we are doing the world's work 50 weeks in the year, we want to be handily situated for reaching our desk or bench. If a man lives in the city, he pays a high rent and takes Irish views of the landlord question. If he lives far out, and wastes his time in travel, he is in hearty sympathy with the eight hour movement. I look upon electric roads, therefore, as likely to prove a beneficial agency in the more equal distribution of a happier population around any centre, thus increasing the return on outlying property, while, by the encouragement of retail trade, enhancing the profit of the area lying within the region thereafter more legitimately restricted to business occupancy. I have watched with much interest the manner in which electric roads have already thus developed suburban areas. Booms are not a particularly healthy feature of progress, but they may be, and not infrequently are, genuine and real; and I know nothing more likely to bring on a real estate boom of the best character with permanent results than the installation of a well-managed electric road, enabling a man to leave his work at 6 o'clock, and be sitting down to his supper seven or ten miles out, if he wish, under his own roof-tree, at 6.30.

Having thus discussed the effect of electric roads on the community and on the individual citizen, I will add a word as to their effect on the wonderful impersonal entity, "capital." If all that I have said be true as to the general benefits, it follows that the wealth and ease of the community are materially increased; but what I refer to now, is not the direct enhancement of values, so hard to trace out, though so palpable, but the stimulus given to saving habits by the better opportunities of investment. Careful analysis of the working of electric roads goes to prove that when operated with skill and discretion, they are 50 per cent. less expensive to run than horse railroads are. What does this mean? One thing it means is that many roads can be built that would be out of the question with horses. Another is that roads not paying can be placed on a dividend basis. In 1888, out of 19 horse roads reporting in New York city, 10 showed a deficiency. Last year their net earnings were much better, but it is evident that a horse road is not always a mine of wealth, though it may be of fertilizers. A third point is the establishing of a new class of investments of a solid, enduring nature. It is within everybody's knowledge that the accumulation of capital tends constantly to the reduction of interest to a minimum. There was a time when the long stocking and the iron chest were the common bankers for the savings of the timid; and the capital that was bold earned the double reward of its bravery and scarcity. As Walter Bagehot, the economist, has remarked, the English people have always wanted to put their money into something safe that will yield five per cent.; and this is undoubtedly one reason why English capital, free and fluent, is so much a power in the finance of the world, and why so much comes this way. As Mr. Bagehot says:—"In most countries, most men are content to forego interest; but in more advanced countries at some times there are more savings seeking investment than there are known investments for." It is thus in America, so far as "safe" investments are concerned, and by safe I mean such as do not require the active care and ceaseless thought of the capitalist, but may be held by trustees, widows, hospitals, universities, savings banks and the like. The competition of capital for the best class of government bonds, municipal bonds, railroad stocks, &c., has reduced the earnings on these to a very low figure, whether in America or England or Germany; and the result is that we see to-day, as never before, the planning of enormous trusts and gigantic industrial enterprises, which represent in no small degree the endeavor of capital, or savings, still to enjoy its wonted income, but in newer fields. Now I look upon the street railway business of the country, under the regime of electricity, as offering one of the best opportunities for local capital, and for what may be called the organization of local savings, which might otherwise lie around in napkins, like the unjust steward's talent, and be of no use to anybody. The capital in street railways in America to-day, reaches from $175,000,000 to $200,000,000. If the statement I have made as to the superior economy of electrical power be true, how much greater becomes the earning capacity of this investment, and how much greater are the attractions held out to construct the hundreds of new roads that are still wanted and will be called for as our towns and cities grow. Of course, I am aware that it may be said that this showing might lead to a demand for lower fares. It might, but the public is intelligent enough to know that other things are more necessary, such as better cars, with better heat and better light; improved tracks, faster running time and shorter headway; so that the 150,000,000 passengers on the street railroads every year may travel in all safety and comfort. Street railroads are peculiarly suitable as a field for local investment. Their operation can be watched all the time. They run under a man's eye when he is on the street, or past his window when he is home. He knows something of their officials; he can influence the domestic legislation they are subject to; he can assist in more ways than one to swell their earnings.

The next important point to which I would direct your attention is the effect that the electric railway has upon the employés of the service. It cannot be denied that the introduction of electricity in this respect marks a decided advance in the social condition and aptitudes of a large body of men. I have never yet met with anybody or anything that could place the work of a horse car driver in a favorable light. One certainly could not fairly expect a man who spends the day with his nose at the tail of a car horse to realize a very high ideal of life and duty, especially when the whole of his work is done under conditions exhausting alike to temper and physique. It is out-door exposure the whole time, whether in summer heat or winter blast. Half the time it is an exercise of sheer brute strength, and no car driver believes in his heart that a horse-power is only 33,000 foot pounds a minute. His aching wrists and dislocated shoulders tell him that Watt was far below the mark in putting it at that figure. And then, the worry of the street traffic. We have all of us noticed the conscientious persistence with which draymen and coachmen will keep on the car tracks in front of a car. An investigation made two or three years ago in Chicago showed that at one point in the streets there, 97.6 of the street traffic sought the railroad, while at another it was 87½, and at a third, 90 per cent. Against such odds the driver with his restless or apathetic team has to make his way and keep to the running schedule; fighting all the time with the fear of an accident either to his car or to some hapless foot passenger.

With an electric car, the matter is not one of muscle and brawn, but of average intelligence and ordinary readiness of decision. A better class of men are wanted and forthcoming, or the same men are relieved from physical wear and tear, and thereafter can earn their bread in the sweat of their brow and not that of their body. A woman might easily run an electric car. The motorman gets instantaneously by the turn of a switch the exact degree of power that he wants; he can apply his brakes readily; and if he needs to run backward up-hill he can do so, sitting down at his switch. It is not necessary to expose him to the weather. His fears as to running people down are materially lessened by the gain in control of the car and by the further fact that an electric car takes up only half the space on the street that a horse car and its team do. The work is not less safe than cleanly. You may remember that when steam roads were started in South Carolina, one of the negro drivers tied down the safety valve and then sat on it. As a result, cotton bales were placed between the locomotive and the coaches to protect the passengers in case of explosion. The new driver was, however, still on the wrong side of the bales. In electric cars both driver and passengers are free from harm. John Bright once said that the safest place on earth was a first-class carriage in an express train; but to-day it may be fairly affirmed that no vehicle can compare as to freedom from danger with the electric street car.

A feature of this refinement of the work is that it must necessarily be attended by better pay for the higher intelligence and skill. Mere brute strength does not command good wages nowadays, except in a prize fighter, and the further we get away from animal conditions the better do we find the status of the individual or the occupation to be. The remarks made above as regards the drivers apply equally to the staff at the generating plant. People sometimes wonder why there are so many hostlers around car stables, but when you remember that well-kept car horses work only two hours and a quarter daily, you will see that they need a good many attendants at the stables during the other 20 odd hours. In place of these grooms and hostlers you have, with an electric plant, a skilled force of steam engineers and mechanics, each trained for the special function which the principle of the division of labor has shown him to be best qualified for.

And here let me inject the pertinent remark, that this new and successful development of electricity is one reason more why the mechanical engineer and steam engineer should master electrical principles and practice, whether for the higher walks of his profession or for the humbler duties of running a plant. The coming of electricity, and its application to light and power, has afforded a grand stimulus to steam engineering in every department, and may not improperly be claimed to have created the modern high speed engine. Sir William Thomson has said that the electrical engineer is nine-tenths a mechanical engineer. To this I will add a corollary, and say that the mechanical engineer may be a master in these new electrical fields if he will only add the one-tenth to his education. The time is at hand when the mechanical engineer will not be considered worthy of his name or his calling unless he is also an electrical engineer, as familiar with Ohm's law as he is with Carnot's or Mariotte's.

Incidentally through this paper I have referred to the effect of the electric railroad upon horses. It has, indeed, been most gratifying to see how readily the electric railroad has rallied to the support of the Humane Society. It is a humane society itself. Whether he wished it or not, the electrical engineer in this instance is conferring a great boon on the horse. We sometimes do the greatest good, as we do often the greatest evil, unconsciously, rather than of set purpose; and so, here, the inventors of the modern electric motor and the electric car have released the horse from one of the most painful and exhausting services that it was ever put to. Investigations over a long period have shown that with the pavement dry a horse would meet with an accident in every 78 miles of travel on granite; in every 168 miles with the pavement damp, and every 537 with the pavement thoroughly wet. Unfortunately for the horse, though happily for the rest of us, the first two conditions generally prevail on our streets; and hence the horse has a poor outlook as to accidents. But it is not the accident the horse has so much to dread, after all, as the constant strain and the pull of a heavy load from its dead rest every few hundred yards. It is generally admitted by street railway men that car horses fail because of this feature of their work, and that it helps to cut down their railroad life and utility to the average of from three to five years. If you want to see these conditions at their worst, take Broadway, once our pride, now one of the most overrated thoroughfares in Christendom. The pavement is abominable, and the horses, like the foot passengers, can be seen struggling for a grip on the uneven, slippery stones, all the way from one end of it to the other. The traffic on the street is so great that I have noted full cars making a dozen halts and starts from dead rest between Chambers and Barclay streets,—two blocks. It does not require an expert to foresee the effect of such wear and tear on animals. In Cincinnati, recently, on installing an electric equipment, a street railway company advertised its horses for sale for family and carriage purposes. I have not observed any such advertisements in New York city. The street railway managers are more modest or more truthful here than they are on the banks of the Ohio. The only persons likely to regret seriously the departure of the street car horses from this city would be the horse dealers and feed supply houses, and possibly the street cleaning contractors, though they get their pay anyhow.

I might point out that as a further offset to this displacement of a certain amount of labor in an elementary form, whether that of the horse or the human being in charge of him, we have the stimulus given to a higher class of labor, not only in the station engineer, and motor car driver, but in the electrical expert and inventor. Society benefits greatly by this, just as it does by the superior skill and efficiency implied in the maintenance of such a system as that of the Pennsylvania Railroad company. The running of express trains and fast steamships demands the exertion of the best qualities of a man, as well in the conception of ideas of improvement as in the details of solid construction and vigilant management. Here, therefore, we strike at once into a new field of design and invention, one that promises to be as large and fruitful as any other known to the application of electricity. There have already been several hundred patents taken out on the special subject of electric railways, and the whole air is alive with rumors of the ideas and inventions assuming shape. In a year or two it will be a wise motor that knows its own father. Each new step is a prophecy of a dozen more. Each new patent is a "father of its country," a germ of endless fertility. We begin to learn our resources. "Is there any load that water cannot lift?" asked Emerson, "If there be, try steam; or if not that try electricity. Is there any exhausting of these means?"

Now and then I hear the objection that people would be the quicker to adopt electric locomotion if it were not so beset and made costlier by patents. This is not true, and I have no patience with the spirit that begrudges the inventor his reward. Why do we use the great inventions? Simply and solely because they effect an economy for us in some way or other, chiefly in time or money. If they did not, we should care little about them, and the inventive geniuses of the day would be mere common clay to us. But, on the contrary, the inventor is revered and admired, and is encouraged by the wealth and fame he can earn. Occasionally one hears the expression of an idea that the inventor is wanting in public spirit and devotion to science because he takes out patents and does not invite the world to revel in the riches he reveals while he is content to starve over a crust in a garret. A few weeks ago, Mr. Edison told me that he had found one of his greatest intellectual pleasures in reading "Evangeline." But why should it be less public spirited for Edison to secure a patent on his phonograph than for Longfellow to obtain a copyright on his poetry? Why should not Bell have a patent on the telephone when Victor Hugo protects his "Notre Dame?" Is it not as right for George Westinghouse to derive a princely income from his life-saving air-brake as for Gilbert and Sullivan from their comic operas? Shall not Elihu Thomson enjoy some revenue from his new art of electric welding, as well as Bronson Howard from his "Shenandoah?" It is time that the ideas on this subject were set in the right perspective. Our inventors enjoy the benefits of the patent system because, like the novelists, the poets, the musicians and the artists, they are public benefactors. They promote the public welfare, add to the public comfort, increase the public wealth. The field of electric locomotion will be but one more opportunity to demonstrate this truth. There is no patent on the horse, but the patented electric motor can beat him on every point every day in the week.

Such then, are some of the reflections to which our subject invites us, at this early stage of its development, and there is but one other point to which after this section, I shall refer in closing. Before I leave the electric street railway, I would again say as I said at the outset, that I am not presenting this latest application of electricity as perfect. It is not; on the contrary it is in development and improvement under our very eyes. It is endeavoring to harmonize with its environment. The questions and problems that it opens up are very much like the concentric shells of the Chinese ivory puzzle balls; and we have not yet reached their core. It has one or two family quarrels on hand. The telephone is hardly yet on speaking terms with it. But we know fairly well where the solution of each difficulty lies, and we are on the way to it. Nor am I in any sense an apologist for the shortcomings of our pioneer work. Electric railroad men have made mistakes, are making them now. That cannot be helped. Heaven save us from the men who cannot make mistakes; they will never learn. The conditions in electricity as an industry change with lightning rapidity. A Russian general once remarked of the political situation in Central Asia, that it changed every minute; and so it is in regard to the onrush and uplift of electrical discovery and enterprise. This very fact explains why much of the earlier electric railway work has been of an unfinished, unkempt kind. Mr. Charles Francis Adams, some years ago, in his interesting little work on railroads, said:—"It is a matter of curious observation that almost uniformly those early railroad builders made grave blunders, whenever they tried to do their work peculiarly well; they almost invariably had afterwards to undo it." This is not an excuse, however, for slovenly work. It is better to make blunders trying to do well than in lazily neglecting one's duty; and though it hurts a man who built for eternity to see his work ripped out in five years, he has the serene, sustaining consciousness of right effort and honorable performance. The electric street railway will the sooner achieve its social destiny if the engineering done upon it be the highest and best that the art at each instant will allow.

The topic I have reserved for brief final mention is that of electrical long-distance travel. This is the department of the subject in which imagination has not yet sobered down into invention. Our fancy still plays around the possibilities, and so far from realizing the social side of teletravel, people have not yet awakened generally to the idea that it has any serious, practical side at all. Our patriarchial poet, Whittier, expressed his surprise a month or two ago in his "Burning Driftwood," when he wrote:—

> "Far more than all I dared to dream,
> Unsought before my door I see;
> On wings of fire and steeds of steam
> The world's great wonders come to me."

The steeds of steam are now an old familiar story; but the mechanical Jay-Eye-Sees of the coming day bid fair to be those with "wings of fire;" and then our speed may be something more nearly approximating that of light. It is amusing, however, to see how quickly our generation has become accustomed to teletravel. Did not the Royal College of Bavarian Doctors seek to forbid railway travel because it would induce *delirium furiosum* among the passengers, and drive the spectators crazy? Did not an English quarterly say: "We would as soon expect the people of Woolwich to suffer themselves to be fired from one of Congreve's rockets as to trust themselves to the mercy of a machine going at the rate of twelve miles per hour?" And did not our own General Webb in 1835, after a railroad journey, with ladies, from Boston to Providence, exclaim in horror: "To restore herself to her caste, let a lady move in select company at five miles an hour, and take her meals in comfort at a decent inn." Such alarming and conservative extracts have a familiar sound, perhaps, but I can assure you that they are positively of the ancient date mentioned and not extracts from recent New York newspapers. The fact remains that to-day we have ceased to regard a speed of 60 miles an hour in railway travel as extraordinary, and are casting about for the means with which to attain a higher rate even than 75 miles, of which record was made in 1886, on a short run. This acceleration is, it appears probable, to be found best, or only, in the use of electricity, for the reason that the electric motor may drive directly on the axles, that it need not offer much resistance to the air, or smash the track, and that it does not have to carry its own supply of fuel and water. There are men in this audience who have seen such an electric locomotive making with ease 120 miles an hour, and who propose to propel it at 180 miles an hour. If these things be so—as they are—we know that with electric teletravel, the public will have to accustom itself to strange new conditions, exceeding in scope and power those of the last fifty years. The change will come in our time, and the present telegraphic and telephonic facilities are but an education for it. When we can talk instantaneously with friends in Boston or Philadelphia over a wire, we resent the inadequacy of the means of fast and far locomotion that should enable us to meet them face to face if we wish to do so. When we see electric cars in our streets traveling easily at 15 and 20 miles an hour, and know that on a clear, unbroken, straightaway track we could go from New York to Philadelphia or Boston with the same agency and kindred apparatus, in about an hour, American ingenuity and enterprise will not rest until the thing is done. That will be the first stage in the next evolution of travel.

At the present time electric street railroads are running or building in nearly 150 of our towns and cities, with some 2,000 cars on about 1,200 miles of track. So far as urban traffic is concerned, the new departure has been made. Electric locomotion is with us, an assured fact, the most civilized form of travel, as the electric light is of illumination and the telegraph or telephone is of communication. Already over 150,000,000 nickel ballots are being cast yearly in its favor, and the welcome to it is universal. In the northwest that brand-new cable plant costing $400,000 has just been thrown aside to make room for it. In the south, it is saluted with the exclamation of the delighted darkey,—"First dey freed de negro, and now dey freed de mule." In New York we are waiting on Providence and the aldermen, but we shall not be satisfied till this city is abreast of other progressive communities in the adoption of that which has given, in so short a time, so many proofs of its ability to promote in every respect the highest social welfare of the citizen.

The address was followed by the exhibition, with the aid of the magic lantern, of over 50 views of electric roads in as many American towns and cities, and of the leading systems. These views were explained with running comment.

.... THE grand truths of physical science should be the talk of every schoolboy.—*Professor W. A. Anthony.*

.... IN every well-regulated boiler room, each day's coal should be weighed, not guessed at.—*A. F. Upton.*

.... IF the army of would-be inventors could enter the field with a full knowledge of what science has already done, the conquest of new territory would be still more rapidly accomplished, and not a few of those whose names would be remembered, would be found to have come up from the utilitarian ranks.—*Professor W. A. Anthony.*

ENGLISH AUTHORITIES ON HIGH-TENSION UNDERGROUND CIRCUITS.

During the recent sessions of the New York Senate Committee, which inquired into the condition of the electric lighting circuits in New York city, there were submitted to it the answers given by a number of prominent English electricians to a series of questions, relating to the practicability and safety of underground high-tension circuits. These questions were prepared by Professor Henry Morton. and the answers to them are on file in the Stevens Institute of Technology. As the questions are of general interest at this time, we print them below together with the answers given to each :—

Q. 1. *Can high tension direct and alternating currents for lighting and power purposes be safely and successfully distributed by means of underground cables? If so, up to what voltage can this be done?*

Sir William Thomson—Yes, I believe so, up to 2,500 volts.

Professor George Forbes—We have ample proof that high pressure electric currents, either direct or alternating, can be distributed safely and successfully, for lighting purposes, by means of underground cables. Our experience in the past has been limited to 2,500 volts, as a maximum, and up to this pressure there has been no difficulty whatever, in any case where care has been taken to secure a good and durable type of insulation to the conductors, and to protect them from mechanical, chemical, and other sources of deterioration. It would be unwise to hazard an opinion as to the highest pressure which can be properly used in underground electric mains, until we have experience to guide us. While we have ample data as to insulation and durability under ordinary conditions, yet there are certain phenomena, of whose existence we are aware, when very high pressure (say 10,000 volts) are used, which may, or may not, create difficulties with these high pressures. Until we have further experience, I would not advise any one to run the risk of making the supply of current irregular through defective insulation, and for this reason I would not recommend, at this date, the use in underground mains of a higher pressure alternating current than 2,500 volts, except in way of experiment.

Dr. John Hopkinson—It has been conclusively proved that alternating high tension currents can be supplied without inconvenience by means of underground conductors if the work is properly done; it has also been proved that this can be done with a potential of 2,400 volts. So far as I know it has not yet been proved that a potential of 5,000 volts can be safely used. This potential, however, is now under experiment.

W. H. Preece—I see no difficulty whatever in maintaining such a system of distributing currents by underground cables, and I form that opinion from actual experience and not from mere theory. Underground cables are safe, durable and efficient. I have had full experience of a high pressure alternating current system in Eastbourne, where such a system working with a voltage of 1,800 volts has been at work since 1886, without a single accident or failure, and is now feeding 2,600 lamps. A similar system of which I have had similar experience has been applied in London at the West Brompton Central Station; 1,800 volts have been distributed for over twelve months through 16 miles of underground wire for lighting purposes throughout the rich and flourishing neighborhood of Kensington without a single failure.

I have been a persistent and consistent advocate of the high tension system of distributing electrical energy for many years. In a discussion which took place at the Society of Telegraph Engineers and Electricians on April 24, 1884, I said :—

"I do not think it is practicable or possible with the figures before us, to light up large areas on any such plan as that which has been conceived (a low tension system). It has been departed from in America, it has been departed from in suggestions here, and the day has come when, if electric currents are to be distributed for economical purposes, for lighting or other purposes, they are not to be distributed by enormous conductors swallowing up capital and ruining everybody, but they are to be smaller conductors in which high tension currents can be utilized and distributed. It may be by secondary batteries, when secondary batteries are made practical. It may be by secondary generators such as we have seen attempted on the Metropolitan Railway, though I do not know that that method has reached its practical stage yet. However, I feel quite satisfied with this, that my figures show that the distribution of electricity for lighting purposes by thick conductors by the parallel system, by such a system as that which has been proposed is, I am afraid, out of the question, because it is financially impracticable."

I have during the six years that have passed since these words were uttered, neither seen nor heard anything to change my views. On the other hand, everything has tended to confirm them. A movement that looks very like an organized conspiracy to decry electric lighting has been operating through the press of this country to impress upon this high-pressure system the stigma that it is highly dangerous to person. Accidents, the result of hurried construction, careless suspension, personal stupidity, and the absence of proper regulations in New York and other cities in the States, have been so magnified that much fear and diffidence in this system have been established. But in England, where the work done is more substantial, where bare wires suspended on poles along our streets are not allowed; where supervision is organized, and where regulations are extant, there have been, during the past five years, only two fatal accidents; and it is by no means evident that even these were due to the high tension system. (I attach a schedule of the accidents that have occurred in all Europe since 1880.) In London, out of 2,338 fires last year, two only were attributed to the electric wire, while gas is credited with 209.

E. Fesquet—Direct and alternating currents of high tension for lighting and power can safely and successfully be distributed by means of underground cables, provided ordinary precautions known to all electricians are taken. In my own experience I have used 3,000 volts. An installation I put up at Tours in France has a primary alternating current of 2,500 volts, and has been running satisfactorily during four years without accident of any kind. The conductors in this case are underground.

Q. 2. *If your answer to question 1 is in the affirmative, state whether your opinion is based upon theory or upon knowledge of what has actually been done. If the latter, give a full statement of the facts upon which you base your opinion, showing, as far as possible, the extent to which high tension currents, both direct and alternating, have been distributed by means of underground cables in the various cities of the United Kingdom and the Continent; the length of time during which cables now in successful operation have been in use; the voltage of currents thus distributed in various cities, and the approximate number of lights operated in various cities by means of such cables.*

Sir William Thomson—My opinion is primarily based on general knowledge of the insulating power of the materials used for insulating the conductors of submarine cables and electric light systems, and on measurements made in my own laboratory of voltage required to break down insulations of different kinds. A very small thickness of insulation suffices to resist 2,500 volts, and practically moderate thicknesses are not broken down with 5,000 or 6,000 volts, and are very safe with 2,500, whether direct or alternating. There has not hitherto, so far as I know, been very much practical experience of 2,500 volts on underground conductors in electric lighting, but I have great confidence that it can be carried out, whether with direct or alternating currents, successfully and with every promise of durability of the materials.

Professor George Forbes—The opinion expressed above is founded upon experience and knowledge of what has been done, and after paying most special attention to this part of the subject for many years, and after having inspected within the last fourteen months the most important electric light works in Great Britain, the continent of Europe and America.

In London, the London Electric Supply Corporation has had several miles of underground cable working at 2,400 volts (alternating) for several years. These cables are of best quality vulcanized india-rubber, laid in cast-iron pipes.

The Eastbourne Electric Lighting Co. began work eight or nine years ago, with 2,000 volts continuous current supplied by underground conductors. At Hastings, the same action was taken at the same time by an allied company. Three years ago the continuous current at Eastbourne was abandoned, and an alternating current of 2,000 volts was substituted, new underground mains being used. During all this time the condition of the cables has been perfectly satisfactory. In each of these towns the circuits cover some 8 to 10 miles, and there has been no case of fire, nor any loss of life.

Another allied company is the House to House Co. in London, which has a very fine central station, working alternating currents at 2,000 volts, and has several miles of mains. These cables are generally copper covered with jute fibre impregnated with bituminous compound, and covered with lead. They are laid in cast-iron pipes, with frequent man-holes.

At Rome, in January, 1889, there were 17 kilometers of underground mains distributing alternating currents at 2,000 volts. These were stranded concentric cables, insulated with impregnated jute, encased in lead, served with protective compound, armorclad with iron strips, and further protected by an outer serving of tarred hemp. These have been at work for over two years, and at the date mentioned (January, 1889) were supplying 9,000 incandescent lamps of 16 c. p., and 200 arc lamps.

At Milan, in January, 1889, there were some miles of similar cable distributing alternating currents at 2,000 volts, supplying about 1,600 lights of 16 c. p.

At Nancy (France), there were 10,000 lights in April, 1889. These are supplied by alternating currents at 2,400 volts, by means of underground mains, to which connections are made every few yards. The mains consist of stranded concentric cores, insulated and protected by iron wire strand.

At Tours (France), three years ago, the mains for working a 2,000 volt alternating system were replaced by cables insulated with vulcanized india-rubber, to the extent of six or seven miles, which have worked satisfactorily.

High pressure continuous currents have been worked through underground cables at the Silvertown Electric Works for about eight years without any trouble. The insulation is high-class vulcanized india-rubber.

Numerous other cases might be quoted. I mention those which have come under my special observation. In all of these cases the cables have worked satisfactorily. There has been absolute safety, hardly ever any irregularity in the supply and remarkable freedom from fires.

Dr. John Hopkinson—In this country three companies are using the alternating high tension current for lighting purposes on a considerable scale, the Grosvenor Gallery Co., the Metropolitan Electric Supply Co. and the House to House Co. At the present time the major portion of the conductors of the Grosvenor Gallery Co. are overhead. The cables are manufactured by the Silvertown company, and are insulated with india-rubber, and carried on separate bearing wires. From the Grosvenor Gallery station this company work at a potential of 2,400 volts. They have been at work since about 1886. So far as I know, only one death has occurred in connection with this system, and that some time ago. In this case a youth appears to have received a shock from the conductor, and to have fallen through a skylight and been killed by the fall; whether he would have been killed or not by his contact with the conductor is unknown. I understand that the Grosvenor Gallery Co. have for two years had a pair of Silvertown cables insulated in the same way in a pipe under St. James' Park, and that this cable has not given the slightest trouble of any kind. The Grosvenor Gallery Co., or rather their successors, the London Electric Supply Co., are establishing a station at Deptford, for supplying parts of London. From this station it is proposed to supply at a tension of 10,000 volts; but, so far as I am aware, satisfactory working has not yet been attained with so much as 5,000 volts.

The Metropolitan Electric Light Co. have at present two stations on the alternating system, both working at 1,000 volts. From Sardinia street at the present time they are supplying about 500 h. p.; from Rathbone place, about 100 h. p. The cables are almost all laid underground. They are Silvertown india-rubber insulated cables laid in iron pipes, several cables in each pipe. With these cables they have had no trouble of any kind, either in the way of breaking down of insulation or of shocks. The experience of this company appears to show that it is desirable that the iron pipe should be cast in a vertical position, by so doing chaplets may be dispensed with, which if present, tend to leave points within the pipes liable to injure the cable.

A Silvertown cable in an iron pipe has been in existence under a potential of 2,400 volts, underground in St. James' Park for about two years.

The House to House Co. have one station at work in London, from which they have about 16 miles of cables. These cables are also manufactured by the Silvertown company and are laid in iron pipes, in the same manner as are the Metropolitan company's cables. The House to House Co. work at a tension of 2,000 volts. They have at present about 6,000 8-c. p. lamps connected up and 11,000 wired. I understand that their maximum output is about 55 amperes or 110 kilowatts. The House to House Co. have also stations at Eastbourne and Brighton, but their London station is probably the best of the three.

Concerning recent continental practice, I am not prepared to answer from my own knowledge.

W. H. Preece—The currents for the alternating current high pressure system in England are safely and successfully distributed both by means of continuously well insulated and properly suspended overhead cables, and by means of thoroughly well insulated conductors buried underground in pipes. The voltage used is generally from 1,800 to 2,400 volts.

E. Fesquet—My opinion is based on practical experience extending over ten years, during which I have been entirely employed in alternating current work. Since 1885 a central station in London has been distributing light by means of alternating current of 2,400 volts and transformers, by means of conductors which are partly overhead and partly underground, the number of lamps supplied being about 20,000. Other companies have since been working in London and provincial towns, with alternating currents of 2,000 to 2,500 volts. One alternating current plant has a tension of only 1,000 volts.

I put up a station in Germany in 1885 when the alternating current used was 2,500 volts. The conductors were overhead—the number of lamps being about 2,500. This station has worked up to the present time with perfect success and without accident.

I also put up a station in Italy in 1885 when the alternating current used was 2,500 volts—the conductors being overhead—the number of lamps about 500. The working has been regular, successful and without accident.

Q. 3. Give some idea of the character of the cables used and the manner in which they are laid.

Sir William Thomson—A great variety of plans may be used safely and successfully for both direct and alternating currents. One method for alternating currents consists in placing the two conductors as coaxial cylinders, having sufficiently thick space between them filled with insulating material; surrounding the outer conductor with a less thick layer of insulating material, and enclosing the whole in a lead or iron pipe. The conductors for this system may be copper tubes, but it is generally preferable to make them of wire strands laid with a moderate twist on the proper cylindric surfaces. The inner conductor should be of six strands laid spirally as close together as possible, on a hempen or other non-metallic core. Each wire should be prevented from metallic contact with its neighbors by slight insulation. This method gives practically absolute security against danger to the public.

Professor George Forbes—The types of cable which have done such good service for high pressure work, are generally known in the trade by the following names:—

(1) The Silvertown vulcanized india-rubber cables.

(2) The Siemens concentric cables.

A year ago I had occasion to draw attention to serious breakdowns in the lead-covered type of cable in the electric lighting system of Berlin. This system is worked at low pressure, and very large conductors must be used. The outside of the cable is some three inches in diameter, and when coiling this on a four-foot drum, I conceive it to be quite possible that the lead is severely strained, and, becoming punctured, admits water. This is not so much to be feared with the smaller cables used with high-pressure currents.

As to the manner of laying the conductors, the Siemens concentric cables being ironclad, and being generally laid under the footway, do not require any further protection. In crossing streets they are generally run in pipes.

The vulcanized india-rubber cables are laid in wooden boxes, concrete troughs, or iron pipes. The last of these plans is the most generally adopted. Vulcanized rubber can only be used when of the best material. It then cannot be excelled. Its quality for durability may be judged by tests of its insulation resistance.

The lead covered cables are now generally drawn into iron pipes.

The weak part of a cable is at the junctions to the service lines. Special care must be paid to the manner of insulating these joints.

Dr. John Hopkinson—I have already indicated the character of the cables used.

W. H. Preece.—My view is that there is nothing more practical than 4" or 6" cast-iron pipes, laid from one to three feet underground in which thoroughly well-insulated and well-protected copper conductors are drawn. There are several insulating materials in the market capable of insulating 2,000 volts, but my experience is chiefly with india-rubber. I see no difficulty whatever in maintaining a pressure of 2,000 volts in underground conduits. It has already been done for eight years in Eastbourne.

N. B.—For 4½ years, 2,000 volts continuous current (Brush) were used.

E. Fesquet—The conducting cables used in England, France, Germany and Italy, by me, have been india-rubber covered cables, not concentric—the latter being laid parallel to prevent induction. When cables are laid underground, I use a cast-iron pipe or wooden trough filled with bitumen, the cable being supported by bridges.

Q. 4. What is your opinion as to the safety to the consumer and the public at large, of the converter or transformer system of electric lighting, involving the use of high-tension alternating currents in the street mains?

Sir William Thomson—With properly laid mains the high-tension alternating currents in the street mains underground, involve I believe no danger whatever, to the public at large. The converter or transformer system can, I believe, be made absolutely safe to the consumers by proper arrangements. It has already been largely practiced in London, Glasgow and elsewhere; and as far as I know, no instance has occurred of any consumer having met with an accident.

Professor George Forbes—Previous to 1885, when a low pressure system alone was available, engineers were in search of some high pressure system which would reduce the copper required to a reasonable amount. Their attempts were mainly in the direction of a parallel series system. But they could not recommend it, because of the danger from defective insulation in the house wiring causing high pressure shocks to the consumers. After the alternating current transformer system had been proved to be efficient, it was accepted as the required solution of the difficulty, because the house wiring is, on this system, completely separated from the street mains. Every one in this country who then came to this conclusion, and has had experience of the system, has been confirmed in his belief that the transformer secured the required safety.

Dr. J. Hopkinson—There is in my opinion no reason whatever why high tension alternating currents should not be used in the street mains.

W. H. **Preece**—I have advised the Metropolitan Electric Supply Co., of London, to adopt the same system, and they are doing so, and I have also advised several local authorities in England to do the same thing, and they are going to do it.

I do not express my opinion lightly on this subject. There are about 30,000 miles of underground insulated wire of the United Kingdom under my control, and I have had 37 years' experience of such wires. I venture to think that this experience is unique in its continuity and extent.

E. **Fesquet**—The converter or transformer system involving the use of high tension alternating currents, can be used with absolute safety to the consumer and the public at large. No accident can happen if well-known precautions are taken, and the neglect of them implies great ignorance.

Q. 5. What is your opinion as to the relative fire danger in the transformer or converter system and in the low tension direct current system, respectively?

Sir William Thomson—In the event of the escape of gas, in the neighborhood of the high tension mains, the high tension alternating current may set it on fire; but probably not so the low tension direct current. Within a house or building in which the electric light is used, the danger of fire is not materially different in the two cases, and in either it may be practically annulled by proper arrangements. I believe also, that the transformer itself, when properly constructed, and properly mounted and guarded, does not cause any danger of fire.

Professor George Forbes— In a low pressure net-work system of mains, the resistance is very low, so that if a short circuit occurs in any house wiring (or, if the mains leak, a connection of the house wiring to earth suffices), it is quite possible to have 10,000 amperes, or more, going through these house wires, previous to the going of the fuse, even if the fuse is in good working order. This current, even if it lasts only a small fraction of a second, is able to cause fire-risks. With the transformer system this is not at all the case. The possible current is here limited by the size of the transformer; in the direct supply system it is limited only by the possible output of the central station. The transformer system is safer, because the house wiring is detached from street mains. If the street mains have a bad leak, a contact of the house wiring with gas or water pipes may cause a fire on the direct system, but not so on the transformer system. With proper precautions, however, strictly enforced, as in England, to prevent a short-circuiting of the house wiring, and to prevent leakage from the street mains to earth, both systems are absolutely safe.

Dr. John Hopkinson—In my opinion there is practically no difference as regards fire risks between the converter system and the direct current system.

W. H. **Preece**—There is no more danger of fire from the one system than there is from the other. Perhaps the low tension direct system is the more dangerous of the two, for its fancied security leads to relaxed supervision, while there certainly are conditions when an intense low tension current is more dangerous than a 2,000 volt alternate current. It is an anomaly, though a truism, to say that where there is most danger there is the greater safety; and the reverse is equally true. The reason is that where there is danger there are precautions taken; where there is supposed safety, supervision and care cease.

The immunity from accidents on our British railway system, and on our great steam shipping lines is an illustration of what results from careful inspection and proper regulations. A first-class railway compartment on the Midland Railway, or a state saloon on an Atlantic liner, is as safe a position to be placed in as in a drawing-room arm-chair. The system of boiler insurance and supervision in this country has an equally striking and satisfactory result. Boiler explosions are very few and far between.

E. **Fesquet**—The fire danger in a properly arranged transformer or converter system, may be made much less than in the low tension direct current system, the large quantity necessarily carried by the latter being always a source of danger; besides, its main system must always be directly connected with the house service, and no amount of protection fuses can alter the fact.

In a direct current system distributing mains and house circuits being connected, it is difficult to detect the exact spot where a leak may have occurred, but in the transformer system, a leak in the conductors inside the houses of consumers, can never be connected with the distributing main, and the position of a leak in this latter is easily detected.

Q. 6. In your opinion, is the converter or transformer an effectual safeguard to protect the user of electric illumination from danger from shock or fire?

Sir William Thomson—In my opinion, the transformer, when properly made, properly mounted and supplied with proper safeguards, is thoroughly effective to protect the user of electric illumination from danger from shock or fire.

Professor George Forbes—If the transformer has its primary and secondary coils made separately and insulated separately, and if fuses are placed in both primary and secondary circuits, and if the mechanical construction is such that there is no rubbing and wearing of the insulation between primary and secondary coils, then the transformer is an absolute protection to the consumer against fire and life risks. All these requirements can easily be fulfilled. Major Cardew's safety device suffices to render even bad transformers a protection to the consumer.

Dr. John Hopkinson—In my opinion a properly constructed converter with a suitable cut-out is an effectual safeguard to the consumer against danger from shock. As regards fire the precautions must be the same as with the direct current system.

W. H. **Preece**—The safety of a high pressure system is entirely a question of precaution, design and care. If the following rule be carried out:—

> "Alternate current transformers must be supplied with two main fuses, double-pole switch, and an *earthing device* on the secondary circuit, all of which must be securely fixed in a water and fire-proof structure (by preference situated outside the premises) placed under lock and key, and beyond the control of any unauthorized person"—

and the work in a house be thoroughly well done and maintained, I can conceive of no danger to person or to building which can arise. The earthing device is a most efficient and satisfactory safety valve. But if maintenance be neglected, if the cheap Jack and the Jerry builder be admitted, if safety devices are neglected, then the electric system can become as dangerous as gas, and the converter might emulate in insecurity the kitchen boiler or the steam pipe.

E. **Fesquet**—Yes. Under proper conditions.

Q. 7. State to what extent the converter or transformer system is now being used in London and other cities in Europe for lighting from central stations, as compared with the low tension direct current system, and in favor of which of the two systems the present development in electric lighting in Europe seems to be?

Sir William Thomson—The present development of electric lighting in Europe seems to be in favor of the transformer system on the whole, because of the facilities it gives for transmitting the electric energy over great distances with moderate amounts of copper.

Professor George Forbes—The best idea that can be obtained as to the relative use of low pressure direct supply, and high pressure alternating current transformer supply, at the present time, is to be got by analyzing the evidence given before Major Marindin, at the Board of Trade enquiry on the electric lighting of London, in 1889. The following table shows the companies which were given powers for one or other of these two systems, the capital which had been authorized, the amount which had been paid up at the date of the inquiry, and the number of square miles in London allotted to them:—

LOW PRESSURE DIRECT SUPPLY.

	Authorized capital.	Paid-up capital.	Area square miles.
Westminster Electric Supply Corporation	£100,000	£8,000	1.5
Kensington and Knightsbridge Electric Lighting Company	250,000	37,240	1.1
St. James and Pall Mall Electric Light Company	100,000	26,000	0.3
Total	£450,000	£71,240	2.9

HIGH PRESSURE TRANSFORMER SUPPLY.

	Authorized capital.	Paid-up capital.	Area square miles.
London Electric Supply Corporation	£1,250,000	£585,000	5.3
Metropolitan Electric Supply Company	500,000	152,732	3.7
House to House Electric Light Supply Company	350,000	41,600	1.1
Total	£2,100,000	£779,332	10.1

The most certain way of judging of the comparative amount of business being done by the several companies is, to compare the paid-up capital in each case. Here we find that the companies working on the low pressure direct supply system had contributed 8.4 per cent. of the total paid-up capital, while those using the high pressure alternating system had contributed 91.6 per cent. of the total paid-up capital. I should mention the fact that a small area was allotted to a company called the Electricity Supply Corporation, but I can find no evidence in the reports as to what system they are to adopt, nor any facts about their capital. The Notting Hill company, so far as I can learn, is not doing anything. The Chelsea company is a high pressure supply, reduced in pressure by batteries.

The general evidence elsewhere in England and Europe generally is, that at present high pressure is most generally adopted, and almost always on the alternating current system. A very significant fact is that Mr. Crompton, who was a most able advocate of the low pressure system, has lately secured the contract for lighting the town of Chelmsford, and has himself selected the alternating high pressure system with transformers. It is my firm conviction that at present and until a storage battery is found which is cheap, efficient and durable, most of our municipal lighting in Europe, including Great Britain, will be on the alternate current high pressure transformer system, and that only in exceptional cases can a low pressure supply be economically given.

Dr. J. Hopkinson—In addition to the alternating current system stations there are in this country certain direct current installations. In London there are the St. James' Co., the Chelsea Co., and the Kensington Court Co. In the provinces there is Bradford and there are other places. So far as I am able to judge there seems to be a somewhat larger application of the alternating current than of the direct in London. Taking the whole of the country it is difficult to say; it is proposed to apply each in many places.

W. H. Preece—The system of distribution in houses is essentially a low pressure system, whether the energy be derived from alternate current converters, continuous current batteries or low tension central stations. The high pressure and supposititious danger are confined to the external mains and feeders, which, if kept underground, can be made absolutely safe.

E. Fesquet—The present development in Europe. including London, is greatly in favor of the alternating system.

Q. 8. *Explain to what extent high tension currents, direct and alternating, are necessary for the successful and economical distribution of electricity for lighting and power purposes, and state what, in your opinion, would be the effect upon the electric light and power industry, and the interest to the public in general, in case the use of high tension direct and alternating currents were abandoned, and all lighting and power work done exclusively by means of the low tension direct current system?*

Sir William Thomson—The mass of copper required for the economical transmission of electric power to distances of more than a mile is so great, relatively, to the value of the work done, if the potential be limited to 100 or 200 volts that in my opinion it would be fatal to the electric light and power industry, and to the interests of the public in general to abandon the use of much higher potentials than 200 volts.

Professor George Forbes—The reason why electric lighting from central stations made no progress in England till 1885, was only in part due to the Electric Lighting Act. It was mainly due to the fact that electricians saw that the copper required for feeders from a central station, to supply 100,000 lamps on the three-wire low tension system, on the most economical principles, must have a total section of at least 50 square inches each, which is impractical. They resolved to wait until a satisfactory high tension system should be worked out. Of these, the parallel-series system could not be adopted, because the house wiring was in direct connection with high pressure mains. The storage battery system might have been used, if the efficiency, economy and durability of these were sufficient for practical work on a large scale. Even now, the secondary battery has not been sufficiently perfected in these directions. If it were it would be very generally adopted. The transformer system is the only one which has satisfied those engineers here who have had experience, as an economical and safe means of converting high into low pressure. For large towns high pressure is a necessity, especially in America, where the houses which are to be supplied are often at great distances from each other. If high pressure systems were abolished in England electric lighting would, from an engineering point of view, be in the same position as five years ago. Central stations could then be started only in extremely concentrated districts where light is used up to late hours.

Dr. J. Hopkinson—The great advantage of the high tension system is that the generating station may be placed at a considerable distance from the work to be done. In cases where the generating machinery can be put close to the work no doubt the direct system would be adopted. But in large towns this is not unfrequently impossible, not alone upon the ground of capital outlay in real estate, but also on the ground that the powerful machinery required would be an annoyance in the neighborhood. Thus, if high tension currents were prohibited it would involve two things for the public, a much greater cost of supply and the annoyance of machinery placed in a place where it is undesirable.

E. Fesquet—The high tension systems, both with direct and alternating currents, are essential to an economical distribution of light and power—the possibility of using water power at a distance is itself an element in the question which is an obvious advantage; even if steam power is used, it can be done more economically outside a town; then the possibility of concentrating at one point the motive power required for supplying a large district with light is an immense advantage from an economical point of view; it is probably the possibility of establishing central stations, to supply large areas from which may be considered to start the general application of electricity. If all lighting and power work were done exclusively by means of low tension direct current the advantages within the reach of all would be withheld until a wiser generation should arise to take advantage of the facilities offered by the high tension system. By every direct system the consumer can use only one kind of lamp; by means of converters the consumer can select any type of lamp.

Q. 9. *Can high tension, direct and alternating currents be safely distributed by means of overhead conductors? If so, under what circumstances, and by means of what precautions?*

Sir William Thomson—Yes, I believe perfectly and easily, except in cities; and even in cities by the observance of the rules for public safety which have been imposed by the British Board of Trade. For the transmission to great distances over the country I believe electric energy can be conveyed by currents, whether direct or alternating, through a pair of bare copper wires, at a distance of from five inches to a foot from one another, insulated by porcelain or glass insulators, and supported on poles, with perfect safety to the public. The requisite security against the possibility of electric damage to man or beast, through breakage of a wire or blowing down of poles, can, I believe, be made practically perfect by proper appliances.

Dr. John Hopkinson—The experience of the Grosvenor Gallery Co. shows that high tension alternating currents can be safely distributed by means of overhead conductors; this has been attained by the use of thoroughly well insulated conductors carried upon independent bearing wires.

Professor George Forbes—High pressure direct or alternatcurrents can be safely distributed by means of overhead conductors, if proper rules are made, and means arranged for enforcing them. In the last five years the central station at the Grosvenor Gallery in London has supplied by overhead conductors alternating current at 2,400 volts to about 15,000 sixteen candle power lamps, or the equivalent. The contractors foresaw that carelessness on their part might lead to accidents, and so to condemnation of their works. The work was all of the best. Best vulcanized india-rubber insulation braided, was used, and the mechanical construction of the lines was excellent. The cables are all supported by insulating suspenders on a steel wire. The supports are all firmly stayed on the tops of houses. Inspection of these is perfectly easy. There has never been a death from shock, except perhaps one, where, however, the sufferer fell from a house roof, and the cause of death was uncertain. Fires on this system have been almost unknown. The rules for overhead wires, prepared by the Board of Trade, are in my opinion more than sufficient for the protection of the public. Æsthetic considerations prevent us at present from suspending our cables on poles in the streets. In towns where elevated railroads are allowed in the streets, I do not think that this consideration need have much weight.

E. Fesquet—I have put up several overhead conductors for alternating current at high tension. The poles I have used have been generally iron, the insulators of porcelain, the india-rubber covered conducting cable has been sometimes supported by a steel wire. Storms that have wrecked telegraph and telephone wires have left my conductors uninjured, and I have never had any accident from the current during my experience of 10 years.

Q. 10. *Kindly make any other suggestions which occur to you which will bear upon the present discussion in the United States as to the conditions under which electric lighting from central stations can be most safely, successfully and economically done?*

Sir William Thomson—The comparatively small currents required in the mains on the high tension alternate current system give it many advantages over all low tension systems; as, for instance, the smallness of the conductors and consequent ease of laying as well as economy of prime cost; and the security against any current strong enough to do damage underground or elsewhere being allowed at any time to pass through them, through any accidental short-circuiting at crossings.

Professor George Forbes—I have been in the United States this year, and seen the condition in which New York City is at present. This would all have been prevented if the electric lighting companies had looked to permanent rather than temporary profits; if the Board of Electrical Control had been composed of able and unbiased electric engineers; or if the civic authorities had not lost their heads. It has been a foolish thing to insist on putting the wires all underground, if the public have a right to expect the most for their money. The cost of electric light will be thus increased fully 50 per cent. What ought to be done is to register every electric light wire, and subject it to strict regulations, such as those issued by the English Board of Trade, under the advice of the Institution of Electrical Engineers. Of course it is only high pressure mains which could be carried overhead for light and power purposes. Low pressure ones would be too large.

If panic legislation were to stop the use of high pressure currents of electricity the public would be largely deprived of a great boon. I must qualify my remarks by saying that in Broadway and many other business parts of New York, where large numbers of telephone wires must of necessity be allowed to occupy the air space, it may be necessary to compel electric light wires to be put underground.

To prevent my remarks in Answer 3 from being the cause of mistakes, I wish to state that in using vulcanized rubber cables the joints must be vulcanized by experienced men.

DR. J. HOPKINSON—In my own practice I am guided in the choice of high or low tension entirely by the consideration of where the generating plant is to be placed. If it can be conveniently placed in the immediate neighborhood of the whole of the work to be done, I adopt the direct system of supply at low tension; if this is not the case, however, I advise the adoption of high tension alternating currents.

W. H. PREECE—It is an absurdity to argue that because alternate currents of high pressure will cause death that therefore electric lighting by alternate currents is dangerous. You might as well argue that it is dangerous to eat food with a knife because a man cut his throat in a fit of jealousy; or that it is dangerous to light a fire because a child burnt its finger by picking up a live coal. Danger depends much more upon the personal element than on that of principle. Accidents in all spheres are generally due to carelessness, recklessness or ignorance. More people are killed by blowing out gas than by electric currents, and there are more people killed by the traffic in the streets of London every week than in the whole of the United States by electricity every year.

Safety (certainly with electricity) is easily purchased by exact design, efficient material, experienced workmanship, proper supervision and careful maintenance, and this can be acquired by high tension alternate currents as readily and as well as by any other form of electrical energy.

E. FESQUET—I consider that substantial, safe and reliable work can be done at prices which will enable a good profit.

CORRESPONDENCE.

NEW YORK AND VICINITY.

The Course of Subway Litigation.—Confirming the Constitutionality of Electrical Execution.—The Edison-Gilliland Phonograph Suit.—Utilizing Niagara Electrically.—The Woman's Exchange Exhibition.

THE fight during the past month for the control of the new electric light subways, cannot be said to have had decisive results, and yet matters have been definitely advanced. Judge Andrews in the Supreme Court has denied the motion of the persistent and persevering Manhattan company for an injunction restraining the Board of Electrical Control from making a contract with the Standard Electrical Subway Co. He holds that such a contract would be legal and would inflict no injury. In the meantime, a stay of proceedings has been obtained. The probability is, that no matter what the arrangements may be, finally, New York will see more subway building this year than ever.

The Court of Appeals at Albany, has affirmed the judgments in the courts below in the Kemmler case, and has declared the electrical execution act to be constitutional. The Court was unanimous. It refuses to do so behind the action or opinion of the legislature in passing the law, as a humane advance, and says: "Whether or not electricity is more humane, was a question for the legislature alone to determine, and they had more chance of so determining than an appellate court." The amusing part of the situation is the manner in which some of the newspapers are now making elaborate preparations for violating the new law, which, it will be remembered, forbids the reporting of executions.

Judge Wallace heard arguments recently in the United States Circuit Court, on the demurrer to the complaint in the suit of Thomas A. Edison against John T. Tomlinson and Ezra T. Gilliland. Mr. Tomlinson was the personal attorney and Mr. Gilliland the confidential assistant of Mr. Edison. Mr. Gilliland had an agency contract with the inventor in connection with the phonograph, and Mr. Tomlinson had charge of the negotiations which resulted in the sale of all of the Edison patents on the phonograph to the Lippincott company organized to make and sell the machines. The defendants received $250,000 in the stock of the company, but Mr. Edison says that he understood that the stock was of little value, whereas the defendants had a contract with the phonograph company under which they were to receive the par value of the stock, so that it is stated, they made $250,000 while the inventor received $500,000. W. Bourke Cockran argued the case for the defendants, and Eaton & Lewis for the complainants. Judge Wallace said that they might hand briefs to him, and he reserved his decision.

The fourth annual report of the commissioners of the Niagara Falls Park, has been submitted to the legislature. The commissioners have located the line for the proposed electric railway from the falls to Queenstown, and will ask a legislative grant of $25,000 for its construction. The commissioners say that the proposition made by some Americans to lease the water power of the Canadian falls for the purpose of getting electricity for transmission to cities and towns as a motive power and for lighting purposes has fallen through. Proposals have, however, since been made on behalf of an English syndicate for the same privileges, and negotiations have just been closed and a deposit of $10,000 made with the commissioners to bind the contract. Whatever these proposals may be, there seems no doubt that the great hydraulic tunnel scheme, a work well within the resources of ordinary engineering, will be carried out in the very near future.

It will be of great interest to electricians to learn that one of the principal attractions of the exhibition of the Woman's Exchange at the Lenox Lyceum, which will be opened on April 7, will be a loan exhibition by Mr. Edison of the inventions shown by him at the Paris Exposition. The extent of these may be understood from the fact that 232 cases have been shipped directly from Paris to the Lenox Lyceum, where their contents are now being placed in position. It was originally intended that the Edison inventions should be shown at the World's Fair, in New York, but as that opportunity of making the American public acquainted with the examples of Mr. Edison's inventive genius is not likely to be afforded, it occurred to the directorate of the Woman's Exchange that the forthcoming display at the Lenox Lyceum would be admirably supplemented by what can justly be regarded as the most remarkable collection of apparatus and devices of its kind that has ever been brought together; and when Mr. Edison was applied to he not only gave his immediate consent to the arrangement, but contributed $5,000 as a donation to the Woman's Exchange. The preparations for the six-weeks' course of entertainment are most elaborate, and include a programme of popular amusements the like of which has seldom been enjoyed in this city.

Professor H. J. Ryan, of Cornell, and a party of "electricals" have been making a tour of inspection through the electrical stations, factories, etc., of this part of the country.

NEW YORK, March 27, 1890.

PHILADELPHIA.

Subway Fighting.—The Lehigh Avenue Storage Cars.—Lighting for Oak Lane.—Western Union Testing its Right to Run Wires on Poles.—Conshohocken First Mortgage Bonds.—The McLaughlin Electric Company.—An Electric Road for Lititz.

THERE will be a lively fight in city councils the present month over the ordinance granting the American Subway Electric Co. the right to lay its conduits in certain streets. It will be a fight between the Edison and Westinghouse companies, and it looks as if the latter would win if it will only use the same tactics that were employed by the Penn Electric Co. to get its ordinance through councils. All the work is underground, and it is hard to convince councilmen that these conduits are necessary. The Penn Electric was badly milked before its ordinance went through, and it looks as if the "boys" intend repeating the operation with the subway. The officers of the American Subway Electric Co. declare that they already have enough contracts with the Westinghouse Electric Light Co. to warrant the building of a concrete conduit over the many miles of streets for which they have made application. Although the conduit will nominally be open to the public it will practically be controlled by the Westinghouse people. The latter declare that they would not build a conduit if they would be allowed to run their wires through the Penn Electric conduits. The latter are controlled by the Edison Electric Light Co., which refused to allow the Westinghouse wires in their conduits, so it is alleged, and this forced the last named company to arrange for an independent conduit. As the Edison company will practically have a monopoly of incandescent lighting in the business portion of the city if the subway ordinance can be defeated it will make a vigorous fight against the measure.

A large number of prominent men, including members of both branches of councils, the directors of public works and safety, members of the bar and large capitalists, visited Germantown Junction recently, at the invitation of the Lehigh Avenue Railway Co. The company proposes to run a line of electric cars on Lehigh avenue, and an invitation was extended to ride on and examine these cars. An elaborate collation was served at the depot at 23d street, after which the machinery of the car was explained by Mr. J. Wharton, who is president of the company. The car is run by means of two motors and a storage battery of 92 cells, which are situated under the seats—42 on each side. The car weighs 12,000 pounds, and can run at a speed of 14 miles an hour, although in the regular use it will be run at six miles an hour.

Oak Lane, a suburb of Philadelphia, is to have an electric light plant before the lapse of many months. There will be a 10-mile circuit that will take in Shoemakertown, Ogontz, Jenkintown and Oak Lane. It is stated that $15,000 worth of stock has already been subscribed for. Over 3,000 incandescent lights have been introduced into private residences. The venture is almost an assured success already.

John R. Read, Silas W. Pettit, George H. Pearson and Wager Swayne, counsel for the Western Union Telegraph Co., have filed a bill in equity in the U. S. Circuit Court against the City of Philadelphia. The bill is brought to test the right of the company to string its wires on poles without the consent of the city.

The Conshohocken Electric Light and Power Co. has decided to issue first mortgage six per cent. bonds to the amount of $20,000, for the purpose of wiping out the concern's floating debt and extending the plant. The Norristown Title, Trust and Safe Deposit Co. has been selected to act as trustee in the mortgage for the bondholders, and to register the bonds.

The McLaughlin Electric Co. filed articles in the Camden county court recently for an increase of capital from $300,000 to $1,000,000. Senator John J. Macfarlane is president of the company, which claims to own a storage battery that will run a street car 80 miles an hour.

The citizens of Lititz have appointed a committee to confer with General Manager Pugh, of the Pennsylvania Railroad, about the construction of an electric railway from Lancaster to Lititz. The cost of the road would be $100,000.

PHILADELPHIA, March 25, 1890.

BOSTON.

Tests of Safety Cut-Outs.—Mr. Dustin Killecutt's New Appointment.—The Wirt System of Car Lighting.—The Russell Arc Lamp.—Col. Hewins on Storage Cars.—Capt. Griffin on Electric Railways.—Peripatetic Cornell Students.—The American Bell Annual Report.—Lighting Public Buildings.—Tests of the Interior Conduit.—W. J. Denver on Telephone Troubles.

Elaborate tests are still being made by Messrs. Brophy and Killecutt, of the Boston Fire Underwriters' Union, on various safety cut out devices for the protection of low-tension small current wires, should they come in contact with high-tension or heavy current wires.

Mr. Dustin Killecutt, for about five years connected with the Boston Fire Underwriters' Union, has resigned his position, and will hereafter represent the Simplex Electrical Co. in New England. Mr. Killecutt's wide experience of the necessities of good work in varying circumstances, and his contact with all the electrical men of New England, should make him a valuable assistant to Dr. Mason, the popular representative of the Simplex company.

THE Russell Electric Lamp Co. has been organized for the manufacture and sale of the Russell arc lamp, one of which is on exhibition at 85 Water street, Boston. The upper carbon is in the form of a disc, about 4½ inches in diameter, while the lower carbon is of the ordinary pencil form, about 14 inches long. With one set of carbons, the lamp will burn 18 to 24 hours, consuming 16 inches of carbon. The disc carbon is rotated by means of a small ratchet operated by a toothed rod, which in turn is operated by the electro-magnets in the case above.

A new system of lighting electric street cars using the overhead or conduit system, has just been patented by Mr. H. C. Wirt, a gentleman who has become widely known as one of the patentees of the K. W. cut-out. At present, when the trolley accidentally comes off the trolley wire, or at the end of a journey when the trolley is reversed, the car is left in darkness. Mr. Wirt's patent is designed to obviate this difficulty. He uses six small accumulator cells, in series with the motor, and the lamps of 12 volts are in multiple with the accumulators. The battery is connected in such a way that the current used in the motor, would charge the battery when no lights are used. When the lights are burning, the current does not pass through the battery, the lights being supplied direct from the line. When the trolley comes off or is taken off the trolley wire, the battery supplies the lamps.

Colonel E. H. Hewins, of the Union Electric Car Co., gave an interesting lecture before the Society of Arts, at the Institute of Technology, his subject being "The Application of the Storage Battery to Street Car Propulsion." The lecture was profusely illustrated by stereopticon views, and by power diagrams, which attracted considerable attention. Mr. Hewins is a firm believer in the storage battery, and brought a large amount of actual experience and close observation to bear on his subject.

Captain Eugene Griffin, gave an interesting talk on electric railways to the members of the Harvard Electric Club this week. He made special mention of the new feature of subdividing the vast net-work of trolley wires into small sections, so that any possible defect in one section would not interfere with the cars on other sections.

Professor E. L. Nichols, of Cornell University, accompanied by a number of his students, has been making a trip through New England for the purpose of inspecting the progress in electrical affairs. While in this city they visited the West End power stations on Albany street and at Allston, the Thomson-Houston factories at Lynn, and made an evening visit to the chief station of the Boston Electric Light Co.

The American Bell Telephone Co. report for 1889, published at length this week, was a grand one. The net earnings for the year were equal to about 26¾ per cent. on the old capital, and rising 21 per cent. upon the enlarged capital. Of the new capital $1,250,000 shared in the dividend of Jan. 15, 1890, and was made a charge against 1889 earnings. The remaining half will participate in the July dividend. The report shows that the telephone business of the country is steadily increasing, that the number of "exchanges," as well as the number of subscribers, is materially greater than a year ago, that the wire mileage is growing rapidly, and that the so-called "long-distance company" is rapidly pushing its work into new fields. In every respect the business of the company seems to be prosperous, and with the exception of the "government suit," which the directors do not seem to have thought worthy of mention, there is no threatening of any consequence.

A committee of three of the board of aldermen, has been appointed to consider the subject of lighting the city hall, old court house, and the registry of deeds building, by establishing an electric plant in the basement of the city hall, to obtain estimates of the cost, and report the same to the city council together with such recommendations as they may deem advisable.

A most interesting and elaborate series of tests of the interior electrical conduit, was made in the Tremont theatre building this week, before the fire underwriters, and the representative architects and builders of Boston. The tests were conducted by Mr. E. H. Johnson, president of the Interior Electrical Conduit Co., assisted by Mr. W. A. Willard, treasurer; Mr. H. M. Underwood, general sales agent; Mr. E. T. Greenfield, electrical construction superintendent, and Mr. George DuBois, general superintendent of construction. A test was made by overheating two rubber covered wires run in ordinary wooden moulding, which had the effect of charring the wood, and in ordinary circumstances might set fire to a building. The same test was then made with wires in the conduit, without any signs of damage to the conduit.

Tests were made of heavy short-circuits, which showed the impossibility of doing any damage to the surrounding property when the wires were enclosed in the conduit. Mr. Johnson showed specimens of the new form of conduit, which is perfectly fire-proof, the whole tube being dipped in an enamel solution which gives it a fire-proof coating. Twin wires are recommended for branches, with very light insulation between, though there may be a rubber insulation over the two. This prevents any possibility of a prolonged arc, which might not blow the fuses, and enforces a quick short circuit, in times of weakness, when the safety fuse will immediately melt. Mr. Johnson afterwards drew attention to a model of the underground system, and explained it in detail. The tests were quite successful and made a marked and favorable impression on the audience.

At a meeting of the Boston Electric Club, an interesting paper by Mr. W. J. Denver, of the New England Telephone and Telegraph Co., was read and discussed. The subject of the paper was "Induction and Interference with Telephone Service from a Telephonic Point." Mr. Denver traced the history of the telephone business and its early trials both by leakage and induction. The first troubles came with the advent of the electric light. All sorts of experiments have been tried to eliminate induction, but up to the present, Mr. Denver claimed that no satisfactory preventive had been invented. He described in detail elaborate tests which were made on the Cambridge division, with the McCluer system, but stated frankly that no improvement had accrued. Other anti-induction devices were tried but all proved failures. Mr. Denver then went on to explain the troubles which had arisen from the electric railways, which use the ground for a return, and quoted widely from papers read by Mr. Preece, Dr. Louis Bell, and Mr. Nelson W. Perry. Mr. Denver, in summing up, stated that the best way to avoid induction was to use a twisted copper metallic circuit, and a balance should be maintained between the two sides of the circuit. Other improvements also should be adopted. Low-tension wires and high-tension wires should be separated from each other as much as possible. In electric light circuits he recommended the transposing of the wires occasionally, and the balancing of the two sides as nearly as possible. In conclusion he said: "I do not know that it is necessary to dwell upon what might be done with grounded wires carrying a high-tension current, except to say that there are good reasons why there should not be any such circuits." The paper was afterwards warmly discussed by Dr. A. F. Mason, Mr. H. F. Campbell, Mr. John C. Wilson, Mr. Alex. P. Wright, Mr. A. C. Shaw, and Mr. George Cutter, of Chicago.

BOSTON, March 25, 1890.

CHICAGO.

City Lighting Operations.—Interference of Lighting and Telephone Service.—Arc Lamp Litigation.—Generating Current by Water Power at Portland, Ore.—Chicago and the World's Fair.—Sewing Carpet Lengths with a C. & C. Motor.—Train Lighting by Carpenter Storage Battery.—The Chicago Electric Club's Library.

ONE hundred and fifty arc lamps on the north side, Chicago, are now supplied with current from the city's new station on Chi.

cago avenue. At present there are in operation eight Thomson-Houston 35-light arc machines. The four automatic high speed engines of 150 h. p. each were made by A. L. Ide & Son. It is intended to increase the capacity from time to time, as appropriations are made by the City Council until 1,000 lights are supplied with current from this plant. The station was so constructed that it will accommodate dynamos sufficient to supply that number of lamps. The circuits are all underground. The 25 miles of cable are of the Standard, Patterson and Cobb types.

The new city station on Throop street on the west side has been finished. The electrical apparatus in the old station on Jefferson street is to be removed to the Throop street power house, and in all 20 Western Electric dynamos will be operated there. This will be the largest municipal electric light station in the city. Prof. Barrett said recently that he could use to advantage $750,000 next year in extending the municipal electric light system.

The Chicago Telephone Company recently notified the city electrician that its service on the north side has been very seriously interfered with since the power house on the north side had begun operations. It attributed its troubles to induction from the city electric light circuits. The telephone lines are overhead and the city circuits underground.

It is predicted that as a result of Judge Gresham's decision, which construed the Brush double carbon arc lamp patent so broadly, considerable litigation may be expected. Actions have been instituted by the Brush Electric Company against the Sperry Electric Company of Chicago, and the Electric Lighting Company of Belvidere, Ill. The latter company uses Sperry apparatus. The Brush company has also begun a suit against the Columbus electric lighting company. In all these actions infringement of the Brush patent is alleged and an issuance of an injunction is asked for.

The Western Electric Company, of Chicago, has brought a suit against the Sperry Electric Company, of Chicago, charging the defendant company with infringing its patent No. 420,109 granted to Charles E. Scribner for a single carbon arc lamp. The patent, although applied for seven years ago, was not issued until January last.

A. J. Coffee, city electrician of Portland, Ore., is a firm believer in the practicability of utilizing the power of Niagara. He cites in support of his faith in the project the success which has attended the use of the Oregon River Falls, twelve miles from Portland, for the generation of electricity. He was recently in Chicago, and in speaking of this matter said: "All the lights in Portland are operated by current generated by the Oregon City Falls. Not only this but the power for electric railways, elevators and small manufactories is obtained from the same source. If this is feasible and profitable there can be no question as to the plan of harnessing Niagara Falls."

Chicago thinks with great confidence that it will manage in its own city the next World's Fair. If by any legislation a change should be made in the programme the Western metropolis would feel as if it had been shabbily treated. Chicago electrical workers are already considering what it becomes them to do to prepare for the great exposition. In fact, a day or two ago, a Chicago inventor informed the correspondent of THE ELECTRICAL ENGINEER that he had already devised a plan for illuminating the fountains during the international fair. It is assumed that now that the fight for the site is over all electricians will join heartily in a movement to make the electrical exhibit the most significant feature of the fair. That the electrical department can be made by all odds the most interesting section can not be doubted. The only thing to fear is a lack of timely action. Electrical workers are so busily engaged that it is hard for them to spare the time to consider what is to be done two years, or more, hence. There is no possibility that there will not be exhibits enough; it is only a question of quality. It is hoped, therefore, that this matter of presenting a display of electrical apparatus, which will represent the best work of American electricians, will be generally borne in mind so that there may be a striking demonstration of the fact that America leads the world in practical electrical invention and application.

An interesting application of an electric motor has recently been made in the wholesale dry goods house of Marshall Field & Co., Chicago. A C. & C. ¼ h. p. motor operates a traveling sewing machine which, as it moves along, sews together the edges of two lengths of carpet. The machine is mounted on bicycle wheels which, as the rubber tires have been removed, fit snugly into a track on the floor. The current is taken from a trolley wire which is supplied from the central station of the firm. The practical advantage of using the apparatus may be realized when it is stated that two machines operated by six boys can sew as many lengths of carpet in a day as 300 girls. Up to the present time it has been found impracticable, it is stated, to sew any of the heavier grades of carpet except by hand.

One of the chair cars on one of the Union Pacific trains is lighted by current from the Carpenter storage batteries made in Denver. The coach has been inspected with considerable interest by a number of experts in Chicago.

The Chicago Electric Club expects to have one of the most complete electrical libraries in the country. Arrangements have been completed by which the books owned by the old American Electrical Society of Chicago will be secured by the club and the library committee proposes to add to this nucleus every standard electrical book published.

CHICAGO, March 25, 1890.

ST. LOUIS.

The Municipal Company's Work.—Electric Railway Extension.—Use of the "Short" Double Trolley Parallel System.—The Citizens' Electric Light Company.

THE Board of Public Improvements are urging the Municipal Electric Light and Power Co. to complete arrangements for a trial of the Jenney low tension and Wood high tension lamps. The Municipal company are making preparations for such test to take place on Delmar avenue, under the direction of the Supervisor of City lighting, who has, by the direction of the Board of Public Improvements, prescribed a rather crucial ordeal extending over a period of some ten nights. Meanwhile the Municipal company are adjusting Wood arc lamps in preparation for fulfilling their contract with the city and are making every effort to complete their plant ready for lighting the city by April 15th. The bill granting the Municipal Electric Light and Power Co. an extension of time for 105 days from January 1st after passing the Council a month ago is still in the hands of a committee of the House of Delegates.

The New American Electric Arc Light Co. of New York threaten suit against the Municipal Electric Light and Power Co. for using the new Wood apparatus, claiming that the new Wood apparatus are infringements on patents which they acquired of the American Electric Manufacturing Co. by receiver's sale. The Municipal Co. claim to have ample guarantee as to such matters from the vendors of the "improved" Wood apparatus.

The mayor has signed the bill authorizing the Lindell Railway Co. to equip with overhead electric power their two Forest Park extensions and main lines except the down-town portion. The new bill authorizing them to equip their down-town lines has been placed before the municipal assembly. Some seventy Sprague motor cars will be put into use during the coming summer.

The Benton Bellfountain Railway have introduced a bill before the municipal assembly asking for the privilege of equipping their road with overhead electric power through the down-town district. They already have a franchise that authorizes them to equip the outer portion of their road with electric power.

The Short series electric railroad on the south end of the St. Louis Railroad line is being converted into a double trolley parallel system. All the mechanical difficulties of the overhead switches have been eradicated.

The Cross-Town Electric Railway was incorporated on the 17th. Capital stock $100,009, half paid up. Stockholders C. C. Carroll, G. W. Brown, P. P. Manion, Given Campbell, D. K. Ferguson and E. D. Meier, purpose to construct an electric railway across town approximately along the line of Eighteenth street.

The South St. Louis R. R. have filed the necessary bond and accepted the franchise which authorizes them to equip their entire road with overhead electric power.

In East St. Louis two factions, the St. Louis and East St. Louis Electric Railway and the Citizens' Electric Railway Co. are striving before the city council for a franchise on the principal streets. The St. Louis and East St. Louis Electric Railway who already have their line in operation across the bridge, appear to be the people's favorite. They have secured the names of some two thousand citizens to their petition. The Citizens' company are not idle and are being backed by a wealthy corporation—the Wiggins Ferry Co. The Belleville Street Railway Co. also ask for a franchise through the city and to connect with the St. Louis and East St. Louis Electric Railway—Bridge Line.

The Citizens' Electric Light Co. began lighting the City of East St. Louis on March 1st under a three-year contract at $125 per lamp for the first 60 lights and $110 for additional lamps when required.

Two additional motor cars have been added to the equipment of the bridge line—the St. Louis and East St. Louis Electric Railway, making a total of six cars. The increased service being necessitated by increased patronage due entirely to the rapid transit and well warmed cars. The Burton electric heaters have given general satisfaction, although owing to the mildness of the winter they have not passed through a very crucial trial.

The St. Louis R. R.—Broadway line—have decided to adopt cable instead of electric power. This change of heart is due to the fact that it is not possible to get an ordinance authorizing them to erect overhead wires through the central portion of the city. They will, however, give the Short double trolley parallel system a trial on the south end of the road, and will probably extend it to their Seventh street section. A bill is now pending before the municipal assembly asking for the privilege of additional tracks on Broadway and Seventh street south of Elm street; the two tracks on Seventh street are to be used as an electric line while the additional track on Broadway, together with the old track, will be cabled. This change will give them a complete double track on Broadway throughout the entire length of their line and renders their road specially suitable for cable work.

St. Louis, March 25, 1890.

PITTSBURGH.

The Rapid Transit Fever and the Duquesne Traction Company.—Report of the Westinghouse Electric Company.—The New Westinghouse Arc Lamp.—Mr. L. B. Stillwell on Light and Power Distribution.

The rapid transit fever which came over Pittsburgh some time ago has now reached the stage of an epidemic. At every meeting of councils a new corporation springs up asking for the passage of certain ordinances granting it divers privileges to operate a street railway. The evident result will be that within the next five years the Gas City will have a street car line on every thoroughfare. At the last meeting of the City Councils alone, eleven street car ordinance were passed, each one referring to a separate line. These lines comprise, however, one system, which is known as the Duquesne Traction Company. The branches are: The Craig Street railway, the Highland Street railway, the Lorimer Street railway, the Howe Street railway, the East End railway, the Wilkinsburg and East End railway, the Wilkinsburg railway, the Duquesne railway, the Market Street railway, the Ellsworth Street railway, and the Negley Avenue and Roup Street passenger railway company. The ordinance of the Duquesne Traction Company grants it the right to enter upon and use certain streets, lanes and alleys and to lease the property and franchise of certain passenger and street railway companies, or either, and to construct and operate, or either, by means of electricity or otherwise, passenger or street railways or either. The company is granted all the privileges that were ever granted to any other similar corporation in the United States on the following and only condition: "That the company shall within 30 days after the passage of the ordinance file a proper written acceptance of it, binding the company to expend in good faith within two years from date, not less than $12,500 per mile in paving with block stone each and every mile of single track of any of the street railway companies enumerated above, which shall be operated, or upon which motive power shall be supplied by the Duquesne Traction Company." The franchises give the company the largest circuit of any street car company in Western Pennsylvania covering in a direct line a distance of twelve miles. The capital stock of the corporation is estimated at nearly $500,000. From what has been learned, electricity is to be the motive power on the entire Duquesne system and whichever company gets the contract of supplying the motors will certainly get a rich plum. The fares are to be five cents over the entire line.

The Second Avenue electric road, a new line, on which the Thomson-Houston system is used, has begun operations. The cars run from Market street, Pittsburgh, to Glenwood, a distance of four miles. The company was threatened with a suit by the Central District Printing & Telephone Co. of this city, but the trouble is said to have been settled. The Telephone Co. alleged that the induction caused by the close proximity of the electric motor wires to the telephone wires occasioned a buzzing noise in the telephones, which greatly impaired their usefulness.

The Westinghouse Electric Company held a special meeting a few days ago and issued the following statement:

Total sales for the year	$4,362,115.22
Cost of manufacture, including material, labor, manufacturing supplies and all royalties paid	2,242,138.30
Manufacturing profit	2,119,976.92
General expenses (including repairs to factory machinery and tools)	767,087.56
Gross profit	1,362,889.35
Lease and rentals (paid to leased companies)	215,555.94
Extraordinary expenses, patent and legal, experimental, interest and discount	407,525.54
Net profits for the year	729,807.87
Sales for six months ending June 30, 1889	1,492,406.15
Sales for six months ending December 31, 1889	2,896,709.07
Total sales for year	4,362,115.22

It will be noticed that the sales of the second half of the year are nearly twice as large as for the first half, which is due to the fact that the leased companies were not in full operation until July 1.

On the evening of March 16, the new Westinghouse arc light system was for the first time introduced upon the streets of Pittsburgh. A large number of the prominent city officials and the representatives of the press were invited. Everything was favorably commented upon by the observers, the steady light of the lamps and the flat carbon feature receiving most of the complimentary remarks.

At the last meeting of the Western Pennsylvania Engineer Society, Mr. L. B. Stillwell, one of the electricians of the Westinghouse Electric Company read an interesting paper on the distribution of light and power by electricity. Among other things he stated that statistics compiled by the secretary of the National Electric Light Association in 1889 showed that there were then in use in this country 237,017 arc lights, 2,704,768 incandescent lights and 109 street railways operated by electricity, covering 579 miles of railway. These represented a capital of $275,000,000 and an engine capacity equal to 500,000 h. p.

Pittsburgh, March 25, 1890.

W. AND DEWEY'S CATALOGUING SYSTEM.

[120.]—It was not my intention to present arguments in my brief note about Dewey's treatment of engineering. My purpose was only to present facts in so lively and vigorous a manner as to call attention to the matter; it appears with some success. If there is any argument, it was accidental, or at most, incidental to this purpose. If there was any indignation, it was only an induction effect from some neighboring circuit; the subject was not the original source of any such energy.

It is not very apparent what the opinion of the surveyors, etc., in the rural districts, whom W. has known, about their titles has to do with the subject; nor that his familiarity with these people has been of great benefit to him in considering it. Commercial importance of a species would be no reason for a philosophic scientist to elevate such species into a genus. But would not the merchant who should arrange his warehouse, inventories, etc., according to a botanical or zoological philosophical system of genera and species, instead of according to commercial importance, convenience of use and customers, etc., be regarded as a pedantic dilettante?

This leads to the only important point in close connection with the subject that I find in W.'s remarks.—Is a system of cataloguing a library a philosophical scheme of human knowledge, for the satisfaction of the logical faculty, or is it a tool, a directory, a means to the easiest, quickest, largest, best use of the contents of a warehouse? W. appears to assume that it should be the former. If it should be so decided, and the requirements of the two should differ at some points, which should prevail? After these fundamental questions, the specific question, whether Mr. Dewey has successfully met the requirements of either, concerning engineering, remains.

W. argues against the differentiation of electrical and mechanical engineering because "a plant may run for months without derangement of its electrical parts," "Its installation is almost entirely mechanical," and "the purely electrical details are so definitely settled beforehand by the laboratory expert or inventor." Who is this inventor, and the laboratory expert? And who is the man that can find the cause of the electrical derangements, when they do occur, and remedy them, and who can intelligently assure the most efficient use of the plant, and the best modifications of it to suit any new conditions or requirements that may arise? W. seems to consider the electrical engineer, "as distinguished from the engineer," as the man who "takes hold" of just what is set down for him and runs it, as long as it is not deranged. This is like calling a stoker, who starts and stops and runs an engine and some machinery, while it is not deranged, a mechanical engineer, but calling the man who can design engines or determine a whole mechanical plant for any purpose a *laboratory expert*, not an engineer.

For the invention and for the designing of electrical machinery, for the designing of electrical plants to meet all conditions and purposes, for the intelligent and efficient management of these, an amount of study of, and familiarity with, a specialty of great extent and difficulty, electricity, is required which makes a large and fundamental differential for electrical engineering. But what large and important subject differentiates the *Roofs-and-Bridges Engineer*, for instance, from the Mechanical Engineer; or the *River-Harbor-and-General-Hydraulic Engineer* from the *Canal Engineer?*

I submit that the treatment of engineering in Mr. Dewey's system does not meet the logical requirements of a philosophical classification, which W. assumes to be the proper test; nor is it, as terms are now used and understood, the best formed tool, directory, or aid to the use of a library.

I. THORNTON OSMOND.

State College, Pa., March 15, 1890.

SOCIETY AND CLUB NEWS.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

At the meetings of the council of the Institute on February 7 and March 18, the following gentlemen were admitted to associate membership :—

Donald B. Heilman, Jonestown, Pa.

Clarence J. Spike, Halifax, N. S.

W. G. Whitmore, electrical engineer, United Edison Manufacturing Co., 65 5th avenue, New York city.

Alfred S. Brown, electrical engineer, Western Union Telegraph Co., 195 Broadway, New York city.

Arthur J. Newell, electrical engineer, R. T. Oakes & Co., Holyoke, Mass.

Michael I. Pupin, instructor in mathematical physics, Columbia College, 68 W. 72d street, New York city.

Arthur E. Nichols, student in electrical engineering, Columbia College, 16 E. 35th street, New York city.

William Elmer, Jr., under-graduate in electrical engineering, Princeton University, Princeton, N. J.

Edward G. Waters, electrical engineer, Thomson-Houston Electric Co., Boston, Mass.

Chas. Steinmetz, electrician, Osterheld & Eickemeyer, Yonkers, N. Y.

Richard Varley, Jr., electrician, Okonite Insulated Wire Co., Passaic, N. J.

William H. Freedman, honorary fellow in electrical engineering, Columbia College, 120 W. 125th street, New York city.

Philip S. Malcom, western agent, Gibson Electric Co., Portland, O.

Charles Henry Davis, consulting electrical engineer, 120 Broadway, New York city.

John M. Fox, electrician, Edison United Manufacturing Co., 133 W. 34th street, New York city.

George G. Grower, electrician and chemist, Ansonia Brass and Copper Co., Ansonia, Conn.

John C. Lee, chemist and electrician, American Bell Telephone Co., Longwood, Brookline, Mass,

William B. Halsey, inspector of lines and instruments of messenger department, Postal Telegraph Cable Co., 94 Leonard street, New York city.

J. C. Bennett, electrician, United Edison Manufacturing Co., 65 5th avenue.

Caryl D. Haskins, electrician, Thomson-Houston Electric Co., Lynn, Mass.

A. J. Lawson, electrical engineer and contractor, Montreal, Canada.

Captain Eugene Griffin, Thomson-Houston Electric Co., 620 Atlantic avenue, Boston Mass.

Edward C. Davidson, of Baldwin, Davidson & Wight, patent lawyers, Times building, New York.

Cary T. Hutchinson, Sprague Electric Railway and Motor Co., 16 Broad street, New York.

Robert Lundell, designing draftsman, Sprague Electric Railway and Motor Co., New York.

Charles L. Cornell, electrical engineer, Western Engineering Co., Kearney, Neb.

Bert Buys, electrician, Rutherford, Boiling Spring and Carlstadt Electric Co., Rutherford, N. J.

Charles N. Black, Princeton, N. J.

A. H. Bauer, electrical engineer, Pullman's Palace Car Co., Chicago, Ill.

Charles F. Uebelacker, Princeton, N. J.

Elmer Z. Burns, consulting electrical engineer, 120 Broadway, New York.

Wm. H. Stadelman, vice-president and chief engineer, Equitable Electric Railway Construction Co., Philadelphia, Pa.

The following gentlemen, already associate members, were upon their application, and the recommendation of the board of examiners, transferred to full membership :—

F. A. Pickernell, superintendent of equipment, American Telephone and Telegraph Co., New York city.

Wm. E. Shepard, electrician, Schuyler Electric Light Co., Middletown, Conn.

Wm. W. Griscom, president, Electro Dynamic Co., of Philadelphia, managing electrician of the Electrical Accumulator Co., New York city.

Gilbert Wilkes, assistant to naval inspector of electric lighting, Navy department, Washington, D. C.

Professor John E. Davies, professor of physics, University of Wisconsin, Madison, Wis.

H. Doijer, assistant in physics, laboratory work, Delft, Holland.

William J. Hancock, superintendent of telephones, department of public works, Perth, Western Australia.

Horace F. Parshall, assistant electrician, Sprague Electric Railway and Motor Co., 16 Broad street, New York city,

Hammond Vinton Hayes, electrician, the American Bell Telephone Co., Boston, Mass.

Frankland Jannus, solicitor of patents, Washington.

Franz Schulze-Berge, assistant to Thomas A. Edison, West Orange.

Wilson S. Howell, central station electrical expert, Edison Electric Light Co., New Brunswick, N. J.

NEW YORK ELECTRICAL SOCIETY.

A visit of inspection was paid by the New York Electrical Society on March 26, to the Equitable Building, upon invitation of the Westinghouse Electric Company. About 150 members and their friends availed themselves of the excellent opportunity thus presented of seeing an alternating current incandescent plant in full operation. The exhibit included the generating plant driven by a Westinghouse compound engine, banks of converters, single converters, the beautiful Shallenberger meters up to the 80-light size, demagnetizing coil, cigar lighter, Tesla motors, stage regulator, lamps, switches and all the other details. Much interest was shown, and innumerable questions were answered by Messrs. Noble, Hubbard. W. Wheeler and others who represented the Westinghouse, United States and Sawyer-Man Companies.

At the last meeting of the Society the following members were elected :

Caryl D. Haskins, Thomson-Houston Electric Co., Lynn, Mass.
A. D. Doman, 36 Union square, New York city.
Richard Varley, Okonite Co., 13 Park row, New York city.
John James, Jr., 64 Madison avenue, New York city.
Chester D. U. Hobbie, Box 722, Yonkers, N. Y.
Chas. H. Kinyon, 84 Warburton avenue, Yonkers, N. Y.

NEW YORK ELECTRIC CLUB.

On Tuesday, March 18, the annual meeting of the club, to nominate officers for the year beginning May 1, was held, and the following gentlemen were nominated. The election takes place April 17, 1890: *President*, O. E. Madden; *vice-presidents*, Grosvenor P. Lowrey, General E. S. Greeley, Erastus Wiman, W. D. Sargent; *secretary*, Charles W. Price; *treasurer*, Willard L. Candee; *board of managers*, J. C. Chamberlain, H. L. Storke, A. H. Patterson, S. Insull, J. J. Carty, J. A. Seely, J. H. Herrick, C. E. Stump, C. H. Barney, H. D. Stanley, Cyrus O. Baker, Jr., Geo. B. Coggeshall, W. J. Morrison; *committee on membership*, Henry Hine, F. Z. Maguire, George T. Manson, George Worthington, Lieutenant F. W. Toppan, U. S. N.

LITERATURE.

The Alternate Current Transformer in Theory and Practice. Vol. I. By J. A. Fleming, M. A., D. Sc. London,, 1889. The Electrician Publishing Co. 487 pp. 8vo. Price, $3.00.

THE construction of alternating current machinery for use on a large scale in electric lighting, has made it necessary that electrical engineers should study far more deeply than they have ever done before the laws of mutual and self-induction, of periodic motion, etc., which, from the fact that they had played so small a part in the practical applications of electricity, had been passed over with only the most superficial study. The student learned that a current when started in a wire induced a momentary current in a neighboring wire forming part of a closed circuit, and that a momentary current in the opposite direction was induced when the current in the first wire was stopped. He knew the effect of approaching a magnet to a coil, of moving two coils to or from each other. He had learned to ascribe these effects to the cutting of "lines of magnetic force" by the conductor, and had learned to compute the E. M. F. developed by a given rate of cutting. He knew that it took time to start a current in a coil of wire and that a current once started could not be instantaneously stopped. But how many appreciated the fact, so familiar now, that a coil in the path of a rapidly alternating current would act as a resistance to greatly reduce the current while consuming very little energy? How many understood that the secondary of an induction coil could be made to give any desired multiple of the E. M. F. of the primary, either higher or lower?

The use of alternating currents for electric lighting necessitated the discussion of such problems as these, and there was a demand for works giving a detailed treatment of the whole subject such as had not before been attempted. Dr. Fleming has come to the front with a work that will be welcomed by every student who has had his attention directed to alternating current phenomena, and by every electrical engineer who has to deal with alternating current apparatus.

In the introductory chapter, Dr. Fleming gives an interesting account of Faraday's original experiments and discoveries in current induction, and shows how Faraday at that time pictured to himself the lines of magnetic force that have played so important a part in the later study of magnetic theory.

The second chapter treats of the laws of electro-magnetic induction. The relation of the strength of induced magnetization to the strength of the magnetizing field is fully discussed, but it is rather strange that the author should not have defined the coefficient μ at the outset, as the ratio of the strength of magnetic induction to the strength of field, instead of treating the total induction as the sum of the lines due to the induction in air and those emanating from the magnetic poles developed on a magnetic body. The idea that iron is more *permeable* than air and that, therefore, a magnetic field develops more lines of force through it, seems so very simple that the coefficient μ would seem to need no other definition than that indicated above, namely, that it is the ratio of the strength of magnetic induction to the strength of field.

Further on the phenomena of current induction are described and the laws fully developed. The self-induction of a circuit is well treated and the coefficient L well defined. The curves of magnetization given in this chapter will be found very valuable, and every engineer who has to do with the designing of dynamos, will find the treatment of hysteresis full of interest. This part of the chapter might be made still more valuable by the addition of data giving the energy dissipated for different degrees of magnetization. The writer has found that much less energy is wasted in the core of an armature when a given E. M. F. is developed by high speed in a weak field than when the same E. M. F. is obtained by a slow speed in a strong field.

Chapter iii. deals with periodic currents and begins with a very clear treatment of the general subject of harmonic motion. Students who have labored over simple harmonic motions in their college courses and wondered what it was all about and what good it could ever be to any one, must make up their minds to master the subject if they would follow Dr. Fleming. They will find use also for the calculus which possibly they did not "elect". The experimental measurement of alternating currents is a most important subject, and here Dr. Fleming has given us a very full discussion of the effects of periodicity upon the indications of the various instruments usually employed.

Chapter iv. begins with an extended account of the experiments of Professor Henry upon current induction. It is gratifying to find in an English book this recognition of the value of Professor Henry's researches. The engineer and the student of theoretical science will find this chapter upon mutual and self-induction, covering more than 150 pages, a most valuable contribution to the literature of the subject. Space forbids any detailed account of the various topics treated in this chapter. The peculiarities of periodic currents are fully considered, including the greater proportional flow through the outer layers of the conductor, the effects of hysteresis in iron cores, the action of "choking coils," and numerous other topics are well discussed.

The fifth and last chapter deals with the dynamical theory of current induction. Here Dr. Fleming endeavors to develop a mechanical analogy to electric and electro-magnetic phenomena and to show, if not what electricity is, at least what it is like. We have been wont to consider the conductor as the seat of the activities manifested by an electric current, although we have known all along that effects were produced in space all around the conductor. Faraday demonstrated long ago that the nature of the dielectric had much to do with the electric forces manifested. Maxwell analyzed Faraday's results and developed the theory of electric displacement in the dielectric. Then, in order to explain electro-magnetic phenomena, he described a mechanical model which fixed the attention upon the action taking place in space outside the conductor. Professor Lodge in a recent work and Dr. Fleming in the work under review, have both in their own ways developed this mechanical conception, and we are led to see that a perfect conductor, so far from being a seat of activity, may be the only portion of space where no action takes place at all. Practical engineers may look upon such speculations as of little consequence, but it is certainly a fact that anything that helps us to a conception of the ultimate basis of electric action helps us to work more intelligently in devising electrical machinery or appliances.

Maxwell's electro-magnetic theory of light is very well treated, and the results of Hertz's experiments on electric oscillations are very fully given. Indeed, Dr. Fleming has laid the electrical fraternity under great obligations by bringing together in such readable form the very latest results and conceptions of the most successful workers in the electrical field. No work that has yet appeared can do so much to enlighten the electrical student upon the modern developments in electrical science. No other can do so much to guide the student out of the old beaten track into the new ways where fresh fruits are to be gathered.

The second volume will be impatiently awaited by every one who has read the first.

.... I SHOULD be glad if it were generally proclaimed that the elementary training in all our science laboratories should be a training in the art of measurement.—*Fleeming Jenkin.*

.... WE do not know whether any molecular motion is concerned in the manifestation of energy which we call electrical.—*Professor John Trowbridge.*

NEWS AND NOTES.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

MEETING OF MARCH 18, 1890.

In the discussion which followed the reading of Dr. Duncan's paper on "Some Tests of Alternate Current Apparatus,"—**MR. NIKOLA TESLA** remarked that Dr. Duncan had brought forward some facts which have not been recognized before; for instance, the fact that the loss in the iron of the converter remains perfectly constant with varying loads, and which he thought ought to be so. In converters in which the primary and secondary are put in the closest possible relation, the increase of the primary and secondary is in an almost constant ratio, and since the loss in the iron is due to something like a difference in action of both currents he thought the loss of the iron ought to be constant within certain limits. With regard to the excessive loss in the dynamo machines in the armature, that Dr. Duncan had found, most of this loss is not due to the fact that we must have that loss, but because we must sacrifice a certain amount for the regulation of the machine. Now, the same machine that Dr. Duncan had tested could be given a greater output and with a loss in the armature of no more than 1 or 2 h. p. But we must work with a highly saturated field in order to obtain a constant potential on the converters. On the other hand, the comparison between the single circuit alternating current and the direct current machine was just, and in the proportion that Dr. Duncan found. On the other hand, if we operated an alternating machine with two circuits, then the output of the machine will no longer be inferior to the direct current machine, but it will be equal to it, if not greater. Now, as regards the general results obtained by Dr. Duncan, he was firmly convinced of their correctness, of course, but also firmly believed that Dr. Duncan had not had the best converter in hand. For he had himself made tests with others of latest make in which the efficiency of such converters was shown to be much higher than is shown by Dr. Duncan. With the improvements made lately he believed that the new converters have now reached a much higher efficiency.

MR. H. WARD LEONARD referred to the theoretical discussion which had taken place in Chicago a few years ago as to the relative merits of the continous and alternating current systems, in which the former had been shown to have a total efficiency of 84.7 per cent., while the latter had been placed at 74 per cent., whereas in his paper Dr. Duncan found it to be only 61 per cent. Mr. Leonard said that the point which was perhaps the most pertinent and which had been pretty well emphasized of late was the fact that the average load of a system of lighting generally through a city is such a very small percentage of the connected devices. He knew of one instance where the lighting had not reached the condition which it will later, as regards supplying a much larger connected load than it has at present, and yet the average load for twenty-four hours was only about 12 per cent. of the connected load. This, of course, brought into very forcible action the efficiency of devices which were low in efficiency under conditions of light load.

DR. S. S. WHEELER referred to a curious case of interaction between two circuits carrying alternating currents, the effect of which was to cause "pumping," that is, aperiodic brightening and dimming of the lamps. These wires were about three miles long and parallel, and after a very extensive investigation it was found that the "pumping" of the lights was due to the alternations on two circuits being nearly, but not quite, synchronous; so that when one set of waves caught up with the set of waves on the next wire while passing them, they first drove those waves ahead and then drove them back. This caused the energy of one circuit to first pile up the energy in the other circuit, and then force it down, and thus cause a pumping effect on the lights. That was overcome entirely by placing the wires in pairs properly. That is to say, the two legs of each circuit had not been arranged side by side; one or two of the circuits had been misplaced. But by bringing those together, so that the negative side or leg of one circuit was right along side of the other leg of its own circuit and not mixed up with the wires of any other circuit, the induction was completely neutralized, and that left the lights perfectly steady.

MR. TESLA, in referring to the point mentioned by Dr. Duncan, viz., how the construction of the converters would be modified when their size is increased, remarked that it was evident that it would be impracticable to increase the size of the converter in the same proportion as its capacity is increased, because as we operate the converters at a constant number of periods we would render a long magnetic circuit transformer very inefficient. A plan was proposed by the speaker a year or so ago to introduce a system in the construction of converters so that all would have the same length of magnetic circuit, no matter whether the converters were large or small. He believed that this would be the proper way of constructing all converters on one system, and that the present method of constructing converters was not right, for every different capacity of converter had a different length of magnetic circuit, and we knew well if one converter is adapted to, say, sixteen thousand reversals, another one with a different length of magnetic circuit is not adapted to the same number of reversals. A year ago they had begun to make all converters of the same length of magnetic circuit so as to render them equally adaptable for the same number of alternations, no matter what their capacity was, so that if, for instance, a converter was wanted that had ten times the capacity of a small twenty-light converter they would practically put in one converter so many multiple circuits as are required to get the capacity desired. Mr. Tesla thought that the results obtained by Dr. Duncan referred to an apparatus which had been in use for some considerable time, but the advances that had been made in that line during the last year alone had been so enormous that one would not recognize this plant at all. Thus the converters at present can be made to have less than half the leakage that they had previously. In other words, it meant practically that a converter could be run with a double load, and likewise the machines had been increased to very nearly double their original capacity.

DR. DUNCAN thought Mr. Tesla's idea of keeping the same length of the magnetic circuit hardly proper. He had worked out the design of a number of converters, and thought that the same period should be retained in the circuit, and the converter should be designed which would give the maximum possible efficiency. For a converter of given capacity one must have a definite period. There is a definite period which, with the given proportions of iron and copper, corresponds with the given capacity of converter; but if we simply increase the cross section of the iron without increasing the length of the circuit we keep the same cross section of copper, which is not a good practice. We have to change both the copper and iron, and he did not think it would be very interesting to design a large number of converters for any given output. As for the efficiency of the plant which was tested, the plant was sent on in November and was supposed to be the latest plant which was produced by the Westinghouse company. He had since heard that the efficiency of the converters had been greatly increased. The losses in the converters could undoubtedly be greatly decreased, especially for larger sizes. As to the relative efficiency of the two plants, it was to be remembered that he had simply taken a 750-light plant, and one dynamo was supposed to be always connected with the circuit in a station of ordinary capacity, that is, of more than twice 750 lamps. We would certainly have the advantage of having at least two dynamos, one of which could be disconnected when the load had reached its minimum, and the efficiency, therefore, would be greatly increased; and also in comparing the efficiency of alternating and continuous plants, we must remember that the business that is catered to by these two plants is very different; that the load diagram of the alternating plant is very different from the load diagram of the continuous current plant. There was a great discrepancy between the curves and the figures of the two. An alternating plant takes up the cream of the business, so to speak. It takes up business in which they get the maximum output for a given number of lamps wired, and in that way we must not calculate the efficiency of the alternating and continuous current plants in order to compare them. If so we are favoring the continuous plant very much. If one can put into a continuous current station an alternating plant which will get business that will pay, it is undoubtedly proper to put that plant in. In the same way, if there is an alternating plant and it is so situated that it can run more economically with a continuous current plant, a continuous current plant ought to be put in. But as the business stood at present a combination of the two plants was undoubtedly theoretically the most efficient.

MR. TESLA, in reply to Dr. Duncan, stated that he proposed not to keep the length the same and vary the section, but simply to vary the section of the copper, at the same time varying the section of the iron. They had plates, for instance, which contain so many multiple circuits. These plates were so made that the coils could be just as well put in as one single circuit transformer, a form of construction invented by Mr. Albert Schmid, of the Westinghouse Co., and in this way they had practically a number of independent transformers, and the only diminution of the capacity of such transformers is that they had a somewhat smaller surface. We might then allow a little higher capacity for that diminished surface.

MR. FREDERICK DARLINGTON drew attention to the fact that one system uses the 50-volt lamp and the other system is forced to use a 100 or 110-volt lamp, and that by the same skill in construction of lamps and the same advance in the art of manufacturing lamps, the 50-volt lamps represent about 20 per cent. more efficiency than the 100-volt lamps. He also stated that they were manufacturing for a considerable time a converter that gave a leakage of .12 ampere on every 40-light converter, and that they had recently, since certain analyses had been made of the iron and the quality and the method of annealing of it had been improved, succeeded in reducing that leakage from .12 to .7 ampere. He also remarked that they were getting out of the total amount of lamps wired on a circuit of the United States Illuminating Co., of New York, 5.8 hours per lamp, which is about 23 per cent. All those points, if taken into account, would, he thought, make the efficiency of the alternating current come much higher than would appear at first thought.

DR. DUNCAN, in reply to Lieutenant John Millis, stated that in England the rate of alternation is determined very greatly by the size of the unit in which the distribution is made. For large units a low rate was commonly employed. It would be found that in most of the continental and English systems the rate of alternations had been decreased as the size of the converter was increased. For a large converter a comparatively low rate should be used, and, as in this country, small converters had generally been employed, the rate was very much greater than if the converter had been large.

DR. MICHAEL I. PUPIN inquired of Dr. Duncan whether he knew of any experiments that had been made lately for the purpose of finding out how much of the lost energy was due to eddy currents and how much to magnetic hysteresis.

DR. DUNCAN remarked that he was not prepared to give any figure on that, because he was experimenting on it at the present time. He was working now to weed out the eddy currents and to determine the effect of hysteresis for different periods of reversal. There were no data at present to tell whether the loss on the iron is due to viscous or static hysteresis. If the change in magnetic force were made at a very low speed then hysteresis due to time would not come in at all; if, at the present speed, it would come in,

MR. LEONARD, referring to his previous remarks, stated that he had been brought to select, in the instance noted, the most exceptional one he knew of as being the future condition of supply of all kinds. In New York City, which, of course, was the most exceptional in the other direction, the Edison station here had instead of five, nearer eight hours average load, which, however, may be somewhat due to the advantages derived from the sale of motive power.

MR. JUSTUS B. ENTZ pointed out that the losses due to eddy currents and hysteresis could be determined by employing different thicknesses of discs and testing in each case.

MR. TESLA stated that the results brought out by Dr. Duncan strengthened him in the idea which he always had, that ultimately the whole loss in the iron would resolve itself into the loss due to the eddy currents. The loss in the iron is constant at all loads; on the other hand, Dr. Duncan finds that the loss is proportioned to the square of the electromotive force, which would be precisely the case if the loss in the iron were due to eddy currents. He thought that an argument for this view.

DR. DUNCAN thought that as for distinguishing between the hysteresis and eddy currents with different thicknesses of plate, unfortunately Ewing had found that, as far as the time hysteresis is concerned, it depended on the thickness of the plate independent of the eddy current, so that it would be impossible to distinguish it in the way suggested by Mr. Entz.

ELECTRICITY AT THE BROOKLYN INSTITUTE.

On the evening of March 21, a meeting was held at the Brooklyn Institute, No. 200 Washington street, in which a Department of Electricity was organized. About 100 members are already enrolled and many residents of Brooklyn and New York, who are connected with electrical work or who are specially interested in electricity, have signified their intention to become members of the Department and of the Institute.

The Department will conduct systematic courses of lectures, accompanied by experimental demonstrations on electricity and its various applications in the arts and sciences; it will provide a laboratory, equipped with instruments of precision for electrical measurements and with other apparatus necessary for the study of electric and magnetic phenomena, that will be open to the members of the Department for experiment and research; it will hold regular meetings for the presentation and discussion of electrical questions; and in general it will furnish those means for the advancement of knowledge in electricity that are provided by similar societies in other cities.

Arrangements have already been made with Professor Robert Spice to give the first systematic course of lectures before the Department on the subject of "Electrical Measurements." The lectures will be very fully illustrated, and will be given on Saturday evenings, beginning March 29th.

At the meeting for organization on the 21st March, Professor Samuel Sheldon delivered a lecture on "The Relative Values of Different Electric Batteries." The lecture was fully illustrated.

All persons who are specially interested in electricity are invited to become members of the Department.

.... SOME may think that an electrician is a narrow specialist. I can only invite such persons to engage in the study of "What is electricity."—*Professor John Trowbridge.*

.... THERE is no teaching more practical, more immediately fertile in results, than that which can be given by the man of science in his laboratory.—*Fleeming Jenkin.*

.... FEW things in physical science appear to me more certain than that what has so long been called electricity is a form, or rather a mode of manifestation of the ether.—*Oliver J. Lodge.*

COLLEGE NOTES.

Massachussetts Institute of Technology.

The new Engineering Building on Trinity Place is completed and now occupied by the mechanical and civil engineers. The structure is six stories high and occupies a space on the ground 148x52 feet. The building is a good example of modern mill construction, though because of its peculiar uses the floor beams and supporting columns are made very massive, much more so than in ordinary factory construction. No attempt has been made at architectural display, but great care has been exercised that the structure should meet its required ends. The ground floor is occupied by the laboratory of mechanical engineering, which is undoubtedly the most complete of its kind. A part of the equipment is composed of a 150 h. p. triple expansion engine, built expressly for the Institute by E. P. Allis & Co., of Milwaukee, Wis. The engine is of the Reynolds-Corliss type with cylinders 9, 16 and 24 inches in diameter and 30 inches stroke; its construction is such that it can be run either single, compound or triple, and with all possible combination of cylinders. This is the first large triple expansion engine ever arranged expressly for experimental purposes, and will allow much work to be done in this laboratory in following out the work begun by Hirn and Hallauer upon simple engines as extended to the triple expansion engine. The steam from this engine and also for the 15 h. p. Harris-Corliss and small Kendall engines, as well as that used for heating the building, is brought underground by a 6-inch pipe from the boilers in the basement of the Rogers building, a distance of about 1,000 feet.

The Harris-Corliss engine is used exclusively for engine tests, and the Kendall for instruction in valve-setting.

A pit contains the necessary tanks, condensers and scales for use in the engine tests. Steam and centrifugal pumps are also provided for testing. A full complement of friction brakes and power scales are provided.

At the front of the building is the applied mechanics laboratory, containing a machine for testing full-sized beams for deflection under given loads and breaking weight, a machine for testing cordage, a machine for testing the deflection of parallel rods and one for studying the twisting of shafts in motion. On the floor above are the offices of the mechanical department and a second room devoted to applied mechanics containing an Olsen testing machine, a machine for testing cements and one for studying the effect of repeated bending upon the elasticity of iron and steel. On this floor there is also an Otto gas engine, a collection of calorimeters of various forms, apparatus for testing injectors and a collection of cotton machinery.

The work in hydraulics is to be much developed, and to this end a wrought-iron tank five feet in diameter and 27 feet high has been provided. The tank connects with a stand-pipe extending to the top of the building, making an available head of about 85 feet. Apparatus will be provided for testing the flow through orifices, over wiers and through pipes, and all the various experiments that can be performed with a moderate quantity of water.

The drawing rooms of the mechanical department, of which there are two, each 96 feet long, together with recitation rooms, occupy the third and fourth stories. The fifth and sixth stories are occupied by the civil engineering department with its drawing and recitation rooms and library.

On the first floor is situated the fan for ventilating the building. It is driven by an independent engine. The heating and ventilating system of the building was designed by Mr. Woodbridge, of the Institute.

The building is to be lighted by incandescent lamps, and for this purpose a dynamo of 500 lights capacity is to be used. The machine is from the United States Electric Lighting Co. Provision is made for an increase of the lighting plant.

The following are the various subjects taken as graduating theses by the fourth year electricals: Messrs. Smith, Blood and Swanton, "A Study of the Efficiency of Alternating Current Transformers by the Calorimetric and Electrometer Methods;" Chas. A. Neave, "Experiments upon Induction Coils for Telephone Purposes;" Carlisle and Clark, "On the Effect of Projecting Teeth in Armatures;" Dunbar and Southworth, "Electrical Methods of Testing Electric Motors;" Baker and Sturtevant, "Tests on Storage Batteries;" Brown and Greenlaw, "On the Leakage of Lines of Force about Dynamos;" La Soeur, "On the Electrolyses of the Halved Salts of the Alkalies;" Mann, "Measurements on Block Signals;" Hall and Raymond, "Tests on a Thomson-Houston Arc Dynamo;" Rice, "A Study of Commercial Current Meters;" Hayes, "A Study of the Effects of Various Strength of Core in Magnetic Telephones."

The Department has received from Mr. L. Prang the gift of a Siemens alternating current dynamo and its exciter of the type used at Mr. Prang's establishment for several years past in connection with the Jablochkoff candle.

The fourth-year electricals are receiving a course of lectures on telegraph engineering from Mr. Jacques of the American Bell Telephone Co.

Mr. H. C. Spaulding, of the Thomson-Houston company, lectured before the Technology Electric Club, March 14, upon electric motors.

Mr. Puffer is giving the fourth-year electricals a practical course in the testing of electric motors by purely electrical methods.

A DINNER TO MYRON D. LAW.

The many friends, professional and others, of Myron D. Law, for nine years the able and popular superintendent of the Brush Electric Light Co., of Philadelphia, gave him a pleasant surprise on Saturday evening last in the shape of a banquet at the Colonnade Hotel, and the presentation of a well-signed letter of regret. When the dinner party came together shortly after 8 P. M., the following gentlemen were present: Myron D. Law, F. A. Lee, J. C. Sager, F. W. Whiting, H. A. Cleverly, J. E. Pentz, W. E. Mellor, C. W. Spear, W. A. Porter. A. J. DeCamp, W. K. Fox, W. A. Drysdale, M.D., C. E. Stump, Wm. McDevitt, L. H. Spellier, F. W. Griffin, H. B. Cutter, A. Shearer, J. E. Shaw, W. S. Griffith, W. D. Marks, D. R. Walker, F. R. Colvin. Letters of regret were read from C. W. Price and W. H. Temple, of New York, and others who could not be present. As to the dinner, the committee spared no pains to make it worthy of the occasion, and the toasts were unusually whole-souled and hearty. The first toast, to the guest of the evening, was, "What is better than good Law? Without it we have confusion; with it all runs smoothly, and system takes the place of disorder. May our guest be a good law unto himself. Parting is pain, but our good wishes attend him. May his new field be a happy one to him, happy to many more whose happiness depends on him." This was responded to by Mr. H. B. Cutter, who formally presented Mr. Law with a handsomely embossed letter of regret signed individually by the entire party. Mr. Cutter fittingly expressed the universal regret at parting with so talented an electrician and so genial a gentleman as the guest of the evening, and wished him God-speed.

After the response to the toast "THE ELECTRICAL ENGINEER," by Mr. F. R. Colvin, Mr. DeCamp was called on and feelingly expressed himself in regard to his loss of one who had worked with him so intimately for the last nine years. At the close of Mr. DeCamp's remarks, he presented Mr. Law with a handsome non-magnetic gold watch from the officers and directors of the Brush Electric Light Co., of Philadelphia. The remaining toasts were responded to by Chief Walker, of the Electrical Bureau of Philadelphia, F. A. Lee, Professor W. D. Marks, Willian McDevitt, C. W. Spear, F. W. Griffin and C. E. Stump. Mr. H. A. Cleverly, though not down on the programme for a speech, was coerced into an impromptu effort that was timely and well received.

At the end of the speech-making, Mr. Law was introduced as "Mr. Myron D. Law, of Denver, Colorado," which introduction was followed by handshaking and a last farewell all around.

MECHANICAL ACTION OF VARIABLE CURRENTS.

M. Borgmann describes in a recent number of the *Comptes Rendus* a research on the mechanical action of variable currents, which forms an interesting extension of the experiments of Professor Elihu Thomson. Lycopodium powder was spread over the surface of a thin layer of mercury lying in a trough placed above a solenoid, through which an intermittent or alternating current was passed. The frequency used was about 300 per second. The powder was found to be set in motion so as to show the existence of two circular mercury currents flowing in opposite directions, and uniting so as to form a diametral current. The effect was improved by making the layer of mercury as thin as possible. Alternating currents gave better results than intermittent ones, and the presence of an iron core within the solenoid much increased the disturbances. It was not found necessary for the mercury layer to entirely cover the top of the solenoid, as the mercury currents could be observed in isolated drops. By placing pieces of metal over the solenoid the mercury currents were changed, and very curious results were obtained by using a ring formed of three equal sectors of copper, brass and zinc. These interesting experiments are capable of a great deal of extension, and M. Borgmann is continuing the research.

GLOBULAR LIGHTNING AT PONTEVEDRA.

D. Ernesto Caballero, professor of physics, and director of the electric lighting manufactory in Pontevedra, recently wrote to the authorities of the Madrid Observatory, giving details of a remarkable meteorological phenomenon which appeared at 9.15 P. M., on January 2d. In a clear sky there appeared suddenly a ball of fire of the apparent size of an orange, which, after falling upon the conducting wires stretched across the city, entered the manufactory, struck the apparatus for distributing the light, from which (after raising the armature of a magnetic circuit closer) it struck the dynamo at work. It rebounded twice from the dynamo to the conductor, and from the conductor to the dynamo, then fell and burst with a sharp detonation without leaving any trace of its existence. Outside the building, and at the moment of falling upon the conducting wires, the ball was seen by (among others) the professor of natural history, Señor Garcéran, and from various effects observed on the wires during the following day there were undoubted manifestations of its electrical origin.

BRUSH'S CLASS OF '69.

The following suggestive little item is from the *Detroit Free Press* of recent date :

A couple of years ago I attended the semi-centennial of Michigan University. There was a large attendance of Alumni and the usual number of class re-unions. Photographers did a lively business in taking groups and among those thus preserved was the class of '69. This class had developed a number of prominent men—ministers, judges, lawyers, teachers, editors, some successful men of business, and several good fellows whose talents had not enabled them to get along very well in the world. Conversing with one of this class upon the mutations of fortune which the race of nearly twenty years had made in a fine group of students, all supposedly on an equality as regarded their running powers, he said: "I will let you into a secret. You observe there in our group Charles F. Brush, the inventor of the Brush electric light. Although we have one or two famous members, he is altogether the most famed as well as the richest man in our class. In college we looked down upon him; we would scarcely acknowledge that he was one of us. Why? Oh, he took the scientific course and we were in the literary department. The literary fellows were the dictators of college life, and set themselves up on a self-supposed eminence that dwarfed all other departments. Not because we had any more talent or worked any harder than the rest, but because it was the notion that a liberal education was a book education, which transcended everything in the way of education and made a marked man of the student happy enough to select the literary course. Ask any of us to-day of our class and the answer is certain to be 'I belong to the Class of '69—Brush's class.'"

WORDS OF GOOD CHEER AND FELLOWSHIP.

To remodel the eminently respectable but slow, easy-going ELECTRICAL ENGINEER, to change it into an enterprising, wide-awake weekly, able to hold its own in a field in which the sharpest competition will be felt, is a task of no mean proportions, amounting, as it does, practically, to the establishment of a new paper. Still the new weekly has many advantages. Messrs. Martin and Wetzler are accomplished newspaper men and genial gentlemen, and their ability and popularity will be supplemented by a liberal policy on the part of the new management. Mr. Phelps is a gentleman of great personal popularity, and he enjoys a wide acquaintance in the electrical field. His newspaper experience has been in the right direction to enable him wisely to manage the affairs of the new weekly. THE ELECTRICAL ENGINEER has our heartiest wishes for its entire success.—*Western Electrician.*

MR. T. C. MARTIN AND JOSEPH WETZLER, former editors of the *Electrical World*, of this city, have severed their connection with that journal, and will hereafter be connected with THE ELECTRICAL ENGINEER, the well-known monthly electrical journal of this city. The ENGINEER will be published as a weekly. The *Review* congratulates the ENGINEER on securing the services of these capable and enterprising electrical journalists, and extends its best wishes for the success of the weekly under its new auspices. Mr. Geo M. Phelps, whose intelligent work as editor of THE ELECTRICAL ENGINEER has been recognized by all, will remain with the ENGINEER as before.—*N. Y. Electrical Review.*

From and after April 1, prox., THE ELECTRICAL ENGINEER, hitherto published in New York as a monthly magazine, will be printed and forwarded to its patrons as "a weekly review of theoretical and applied electricity." As one of the oldest of its class in the American field of electrical science, this periodical has achieved a marked reputation, and in its pages all those who are interested in electrical development may expect to find a safe advocate, exponent and authority, as well as a faithful record of all data and practical accomplishment. The increase in its frequency of publication should also greatly tend to enlarge its circulation and capacity for usefulness, and no doubt this will be the case. The more often that an intelligent journalist can gain the attention of his readers, the more likely is he to enlarge their sphere of understanding and convince them of weighty truths. In these days, when improvement closely follows upon improvement—when new ideas and fresh devices are constantly being evolved—when scientific and mechanical discoveries are daily startling the world—the monthly is too slow a vehicle of intelligence, especially when freighted with electricity. Therefore THE ELECTRICAL ENGINEER does wisely in increasing its usefulness four-fold. The management of THE ELECTRICAL ENGINEER will be vested in Messrs. Geo. M. Phelps, T. Commerford Martin and Joseph Wetzler. Messrs. Martin and Wetzler will have editorial charge of its columns, and bring to their work the necessary energy and journalistic skill to ensure its success as a trustworthy authority in all matters of electrical phenomena and experience. In all respects we anticipate for the paper the kind consideration which it will doubtless deserve. Its office is at 150 Broadway, New York.—*Chicago Journal of Commerce.*

Instances are very rare indeed where the unassuming work of the average newspaper man receives public recognition. When, however, such recognition comes, and it comes spontaneously, it is particularly gratifying. These observations are intended to apply especially to the new departure of our esteemed co-laborers, Messrs. T. Commerford Martin, Joseph Wetzler, Frank R. Colvin and A. C. Shaw, than whom as journalists none are more deservedly popular with the electrical fraternity, and from what we hear they are the recipients of abundant evidence of this fact. We look forward with pleasurable anticipations to the forthcoming issue of THE ELECTRICAL ENGINEER as a weekly under the administration of these gentlemen and that of Mr. George M. Phelps, who continues his interest and identification with it.—*Modern Light and Heat.*

THE NEW YORK SENATE ELECTRICAL INVESTIGATING COMMITTEE'S REPORT.

The Senate Committee on General Laws reported at Albany on March 27 as follows on the electrical investigation :

"The committee has held all its sittings in New York, where the attendance of experts and representatives of the principal electrical companies could most easily be secured. After its first session the committee saw the necessity of having the assistance of an impartial electrical expert, and were fortunate in securing the services of Francis W. Jones, a well-known electrician, to whom we are indebted for valuable advice and assistance. Representatives of the various electric lighting companies, city officials, prominent experts, and others who might be able to give information regarding the recent deaths in New York were called as witnesses. The depositions of Sir William Thomson, of Glasgow, Scotland, (conceded by the experts who testified to be the foremost electrician of the day) Dr. John Hopkinson, Professor George Forbes and William H. Preece, all of London, England, and eminent electricians, were received. These depositions, together with the testimony of several of the witnesses, gave valuable information as to the electric lighting business in the large cities of England and the continent of Europe and the methods adopted there to prevent accidents.[1]

"It appears that substantially all of the electric lighting from central stations in this state is done under one of the three following system : (1) the low tension continuous system ; (2) the high tension direct current system ; (3) the alternating current converter system, involving the use of 1,000 volts or more in main wires, which is reduced by means of converters to 50 or 100 volts on consumers' wires. There are two dangers from electric currents : First, the danger to property from fire, and second, the danger to life from shock. Difference of opinion exists among experts as to what voltage would cause death or whether there is any difference in the danger to life between alternating and continuous currents. It seems to be conceded, and may be taken as a safe rule, that currents of 250 volts or under, either direct or alternating, are safe.

"It appears that 16 persons have been killed in the city of New York during the past three years from electrical currents, most of them being employés of electric lighting companies. Most, if not all of these deaths were caused by a continuous current used for arc-lighting. As far as the committee could ascertain no accident has been caused by underground conductors. The causes for most of the deaths appear to have been carelessness on the part of the electric companies in using poorly insulated or badly arranged conductors, and in neglecting other precautions required for safety. It appears doubtful if an overhead system of wires carrying high tension currents could be, under any circumstances, maintained in the crowded streets of the city of New York without more or less danger to the public.

"The remedy for these evils, in the opinion of your committee, lies in the speedy burial of all electric light and power conductors in New York city and other cities having a population of 125,000 or more, and the enforcement in all cities and towns where central-station electric lighting is carried on, of such rules and regulations as shall compel the companies to properly construct and maintain their plants and adopt such precautions as are required to insure safety to the public. Whatever doubt there may have been heretofore, regarding the desirability of successfully operating underground conductors, has been removed by the experience of New York city with subways and the testimony taken by your committee, which is uniformly to the effect that currents of high and low tension, direct or alternating, may be distributed by means of underground conductors with entire success without interference with telephone and telegraph services and with safety to the public. In the large cities of Europe, underground conductors are, according to this testimony, universally used for the distribution of electrical energy, and in many European cities underground cables, carrying high-tension currents, have been operated for several years with complete success. In cities and towns of under 125,000 inhabitants, where the streets are less crowded, and where overhead telephone and telegraph wires are less numerous, electric light wires may be operated with safety, provided proper precautions are taken. But even in cities of less than 125,000 inhabitants, we believe the interest of the public would be best served by placing electric light wires in the principal streets underground.

"Testimony, including that of representatives of the New

---

[1] See page 176.

York Board of Fire Underwriters, shows that the fire risk in connection with electric lighting is no greater than in the use of gas, if as great. The testimony shows that both the high and low-tension systems can be made equally safe to life and property by the use of proper safety devices.

"The testimony of experts is to the effect that the converter system involving the use of the high-tension alternating current in street mains, affords a system which is, if properly guarded, free from danger to either life or property. It is, therefore, the opinion of your committee that it would be unwise and unjust to the public to restrict by legislation, the danger from high-tension currents used in lighting being admitted; the wires carrying them should be kept out of reach of the public, as should street wires under the converter system. Considering the testimony taken, we do not think it possible for the legislature to form satisfactory rules and regulations for application to an industry which is not only highly technical, but constantly developing and presenting new conditions, rendering the rules proper this year possibly obsolete next year. There should, however, be some form of supervision by properly qualified state or local authorities over the commercial use of electricity analogous to the supervision now exercised over steam boilers. Regulations should be framed with competent expert advice and entrusted to authorities who have power to modify them so as to meet the changing conditions which the rapid growth of the industry constantly brings about.

"As already indicated, there are two questions upon which the legislature might properly act, by providing: First, that no electric-light or power current of over 250 volts pressure be allowed to enter any building; second, that after, say January 1, 1892, no overhead conductors carrying currents for lighting or power purposes be allowed in any street, highway or public place in any city of the state having a population of 125,000 persons or over, and that the local authorities in the various cities coming under this description, in the absence of any state authority, be empowered and directed to make proper provision for the burial of such wires.

"The committee endeavored to secure the attendance of Thomas A. Edison as a witness, but were unsuccessful. Among the witnesses examined were the following: Edward H. Johnson, late president of the Edison Electric Light Company, and Mr. Bowker, first vice-president of the Edison Illuminating Company, representing the Edison interests; Geo. W. Hebard, president of the United States Electric Lighting Co.; C. H. Jackson, president of the United States Illuminating Company; Wm. H. Browne, manager of the United States Light and Power Co., Jacob Hess, commissioner, and Daniel L. Gibbens, late commissioner of the Board of Electrical Control, of the city of New York; Henry D. Kearney, engineer, and Schuyler S. Wheeler, electrical expert of that board; Edward Martin, inspector of the New York Health Department; two representatives of the New York Board of Fire Underwriters, Coroners Schultze and Levy, Thomas Costigan, chief clerk of the District Attorney's office; Professor Plympton, professor of physics in the Polytechnic Institute and president of the late Brooklyn Board of Electrical Commissioners; Dr. Henry Morton, president of Stevens Institute of Technology, Hoboken, N. J.; Dr. George H. Benjamin, electrical expert, and William Maver, jr., electrician of the Consolidated Telegraph and Electric Subway Company of New York.

"In view of the fact that this is the first investigation of the kind ever made in this country, and considering the value of the testimony taken and the numerous inquiries already made for the same from this and other states, it appears proper to ask that it be printed.

"Dated March 21, 1890.

"(Signed)—Geo. Z. Erwin, C. P. Vedder, H. J. Coggeshall, G. G. Van Gorder, Norton Chase, W. L. Brown, Jacob A. Cantor."

Mr. Erwin asked that the report be printed, as there was a general demand for it. A bill was in preparation to meet the suggestions of the report. He moved that the report be adopted. Mr. Jacobs protested that it was too important to be acted on until printed, so Mr. Erwin withdrew his motion, and the report was made a special order for Thursday, April 3.

LEGAL NOTES.

JUDGE COXE'S DECISION IN BRUSH vs. JULIEN.

UNITED STATES CIRCUIT COURT, SOUTHERN DISTRICT OF NEW YORK.

The Brush Electric Co.
vs. } *In Equity.*
The Julien Electric Co., *et al.*

COXE, *J.:*

This is an equity action, for the infringement of four letters patent, granted to Charles F. Brush, for improvements in secondary batteries, and now owned by the complainant. These patents are numbered and dated as follows:—

Nos. 337,298 and 337,299, were applied for June 13, 1881, and were granted March 2, 1886. No. 260,654 was applied for June 13, 1881, and was granted July 4, 1882. No. 266,090 was applied for June 9, 1881, and was granted October 17, 1882.

The first of these, No. 337,298, which is distinguished as Case I., relates to secondary batteries, and consists in a plate or support provided with a mechanically applied coating of absorptive substance to be transformed into an active coating. Also, in a plate or support provided with a mechanically applied coating of granulated, spongy, or porous metallic lead. It further consists in the method of constructing plates for secondary batteries, consisting in mechanically coating lead, or other suitable plates, with an absorptive substance adapted to be transformed into an active coating. The drawings attached to the specification represent the supports in various forms. They show plain, studded, honey-combed, corrugated and ribbed plates; plates with angular corrugations, arranged singly or in pairs, and plates with slots or perforations extending through the plates. The active material consists of granular, porous or spongy lead, which is held in position upon the plain plate of lead by a sheet of heavy paper, card-board, cloth or felt, which may be secured to the plates by rivets, ties, or binding strips of wood or metal. The paper or felt may be dispensed with, and the spongy lead held in position on both sides of the support by subjecting it to pressure, hydraulic or otherwise. In the corrugated, grooved, ribbed, perforated, studded or cellular plates the spongy lead may be held in the grooves, cells, or cavities by paper or felt, or it may be rammed or pressed into them.

The specification states that "when a pair of plates are associated together to form a secondary battery, and immersed in dilute sulphuric acid and charged by the passage of an electric current in the usual manner, one of the plates absorbs a large quantity of hydrogen, while the other plate has its spongy or granular portion peroxidized, and thus forms the oxygen element in the battery."

The claims alleged to be infringed are the first, fifth, eighth, tenth and eleventh. They are as follows:—

"1. A suitable plate or support provided with mechanically-applied absorptive substance and adopted for use as a secondary battery element or electrode after being rendered active by an electric current, substantially as set forth.

"5. An improvement in the construction of a secondary battery element or electrode, said improvement consisting in a plate or suitable support provided with grooves, receptacles, or perforations primarily coated, combined, or filled with mechanically-applied absorptive substance, substantially as set forth.

"8. In the process of making plates or elements for secondary batteries, primarily and mechanically applying or combining with a suitable plate or support an absorptive substance adapted to be transformed into active material, substantially as set forth.

"10. In the process of making a secondary battery plate or element, combining by means of pressure an absorptive substance and suitable material to form a support therefor, substantially as set forth.

"11. In the process of making a secondary battery plate or element, constructing a suitable plate or support with grooves, cells, receptacles or perforations, said plate or support having an absorptive substance primarily applied thereto or combined therewith, substantially as set forth."

The second, No. 337,299, which is distinguished by the inventor as Case J, is for the same invention, substantially, as Case I. The drawings of the two are identical and the language of the specifications is very similar; where it differs, equivalent expressions are employed.

Perhaps the principal differences are the substitution of the words "active material" for the expression "absorptive substance adapted to be transformed into an active coating," of Case I, and the words "lead oxide" for the "granular or porous lead," of Case I.

The specification in question contains this additional statement:—

"Peroxide is the best oxide of lead to use in the preparation of the plates; but as this is rather expensive to prepare, red lead or minium may be used. Some sulphate of lead is liable to be formed when this oxide of lead is employed, by the section of the sulphuric acid of the battery on it before peroxidation or reduction is effected. Protoxide of lead or litharge may also be used, but is objectionable, on account of the large quantity of sulphate of lead which is unavoidably produced by the action of the acid on it."

And also the following:—

"I would have it understood that I do not restrict myself to any particular form of active or absorptive material, or to any particular method of applying it to or combining it with the plate or support, as my invention consists, broadly, in a secondary battery plate or element having active or absorptive material primarily and mechanically applied thereto or combined therewith, as contradistinguished from a plate or element having the active material produced by the disintegrating action of electricity, as in the well-known Planté process."

The claims alleged to be infringed are the first, second, third, sixth, seventh, eleventh, twelfth and thirteenth. They are as follows:—

"1. A secondary battery element or electrode consisting of a plate or suitable support primarily coated or combined with mechanically-applied active material or material adapted to become active, substantially as set forth.

"2. In a secondary battery, an electrode consisting of a plate or support provided with a coating or surface layer of an absorptive substance, such as metallic oxide, applied thereto, substantially as set forth.

"3. A plate or suitable support primarily coated or combined with mechanically-applied oxide of lead or equivalent lead compound, substantially as set forth.

"6. A plate or suitable support provided with grooves, perforations or receptacles, and primarily coated, combined or filled with mechanically-applied active material or material adapted to become active, substantially as set forth.

"7. A plate or suitable support provided with grooves, perforations or receptacles, and primarily coated, combined or filled with mechanically-applied oxide of lead or equivalent lead compound, substantially as set forth.

"11. In the construction of secondary battery elements or electrodes, a plate or suitable support primarily coated or combined with mechanically-applied red lead, substantially as set forth.

"12. The method of making plates or electrodes for secondary batteries, consisting in primarily combining active material with suitable plates or supports mechanically, in contradistinction to forming the active material by an electrical disintegration of the plate or support, substantially as set forth.

"13. The method of making plates or electrodes for secondary batteries, consisting in coating the plates or supports with red lead prior to their immersion in the battery fluid, substantially as set forth."

These two patents, Nos. 337,298 and 337,299, are fundamental patents designed to cover the broad inventions of Mr. Brush.

No. 260,654 is a division of Case J and is distinguished by the inventor as Case J, Division A.

The invention "consists in the method of making the plates of a secondary battery consisting in forming receptacles for oxide of lead in its surface, then applying oxide of lead to the plates and within such receptacles and afterward subjecting the oxide of lead to pressure."

The drawings of this patent are identical with those of the preceding patents, except that Fig. 1, showing the use of cardboard or felt, is omitted.

The specification contains the statements above quoted from Case J, relative to peroxide being the best oxide of lead to use, and says, further, that the oxide of lead may be retained in place by being rammed or pressed into its receptacles, cells or grooves.

The single claim is as follows:

"The method of forming the plates of a secondary battery, consisting in forming receptacles for oxide of lead in its surface, then applying oxide of lead to the plate and within such receptacles, and afterward subjecting the oxide of lead to pressure."

In No. 266,090, distinguished as Case C, the invention consists in a secondary battery element, constructed of cast-lead or other suitable substance, having cells, receptacles, ribs or projection in its surface, whereby an extended surface of metal is exposed to action.

The drawings are the same as those attached to the preceding patents, with some new ones added, showing the plates arranged ready for charging.

The specification says of Fig. 4 that it shows a modified form of ribbed plate resembling an ordinary window-blind with the slats open. It may also be regarded as a thick plate perforated with a series of parallel slots. And of Fig. 5, that it shows the honey-comb form of plate, resembling in construction a simple or double comb of beeswax. It may have its cells extending entirely through the plate.

The plates may be made by pressing plain sheets of lead or other suitable metal into dies or forms by hydraulic or other means, also by slotting, punching or otherwise perforating suitable plates, and also by casting the melted metal into suitable molds.

The claims alleged to be infringed are first, third, fourth, fifth, sixth, seventh, eighth, ninth, twelfth and fourteenth. They are as follows:

"1. In a secondary battery, an element or electrode made up of a series of ribs, substantially as and for the purposes set forth.

"3. A secondary battery element or electrode having its body support or frame provided with ribs.

"4. In a secondary battery, the combination, with one cell thereof of two or more ribbed plates or elements, substantially as set forth.

"5. In a secondary battery, a plate, frame, or other sustaining body provided with ribs or their equivalent, of a less general thickness than the said plate or support, substantially as set forth.

"6. In a secondary battery, a plate, frame or other sustaining body provided with ribs or their equivalents, said ribs or their equivalents being thicker at their bases than at their free edges or ends, substantially as set forth.

"7. A secondary battery element or electrode having its frame, support or body provided with cells or cavities, the walls of said cells or cavities, or the septa, between them having an increasing thickness from their outer or free edges inward.

"8. In a secondary battery, plates or elements provided with comparatively thin ribs, or their equivalents, for surface exposure, and thicker ribs suitably disposed for supporting or stiffening purposes, substantially as set forth.

"9. A secondary battery having a body frame or support of cast-lead.

"12. A secondary battery element or electrode having a supporting body or frame of cast-lead for the active coating or substance, said body or frame provided with ribs or projections.

"14. A secondary battery element or electrode having a supporting body or frame of cast-lead for the active coating or substance, said body or frame provided with slots, perforations, or openings."

The defendants have made, used and sold secondary or storage batteries composed of a series of electrodes, consisting of a cast metal support plate, 96 per cent. being metallic lead, and an exterior spongy or porous coating of mechanically applied active material consisting of lead oxides. These electrodes are placed in an electrolyte of dilute sulphuric acid in water. The charging current converts the lead oxide coating upon the oxygen plates into peroxide of lead, and reduces the lead oxide coating upon the hydrogen plates to the condition of spongy or porous metallic lead. The battery is capable of numerous charges and discharges, in the course of which the active material undergoes successive reductions and reoxidations. The lead oxides used consisted generally of minium and litharge, the former largely predominating in the mixture applied to the oxygen plates and the latter predominating in the mixture applied to the hydrogen plates.

The defenses to all of these patents are anticipation, want of novelty, lack of invention, abandonment (except of No. 260,654), and that the claims have been fatally broadened. As to cases I and J, it is said that the scope of the original applications had been unlawfully enlarged; that the patents expired with an Italian patent to Brush containing the same invention, and, finally, that they are for the same inventions, and that one of them is, therefore, void.

It is also insisted that No. 266,090 is limited by the Italian patent. Invalidity and non-infringement of several claims are alleged.

Are cases I and J for the same invention, and, if so, what course should be pursued regarding them? It will simplify the controversy to answer this question at the outset.

As stated above, the drawings of the two patents are the same, and the language of the specifications and claims are substantially alike upon all matters material.

The contention of the complainant is that Case I is for a secondary battery support mechanically coated with an *absorptive material*, and case J for a similar support coated with an *active material*; "the distinction between the two relating to the condition and inherent capacity of the material of the coating as that material exists at the time of mechanical application." For instance, the spongy lead of Case I has, it is said, no oxygen and is initially absorptive and inactive, while the peroxide of Case J is a fully saturated oxygen compound and is, therefore, active and non-absorptive. It is admitted that the moment a battery, constructed with plates having either coating, is charged or discharged, all distinction vanishes.

"The fundamental distinction between these patents," says the complainant's brief, "is that in the former the coatings of the secondary battery electrodes, are, broadly, mechanically-applied *absorptive substance*, while in the latter these coatings are that class of mechanically-applied absorptive substance defined as active material."

Therefore, both patents, it is argued, are valid.

This question, though it is an accurate statement of the difference between the two, would seem quite tantamount to an assertion that a party may have a patent for a device composed of a combination of iron and wood and a second patent for the same device composed of iron and basswood or hemlock.

One who has a patent for a combination, one element of which is an adhesive substance, may not have a second patent for a combination, identical in every respect, except that the adhesive material suggested must be moistened before it becomes adhesive.

The coatings of both patents being absorptive and active, is the fact that one, prior to immersion in the electrolyte, *has* absorbed, and that the other *will at once* absorb, a sufficient dissimilarity upon which to base invention? Is it a patentable distinction? The difference is one which would hardly occur to a practical electrician, and even specialists enthusiastic in the cause of the patent find it difficult to state it in words which are intelligible to ordinary men. It is too esoteric, metaphysical and minute. It is a mere theory of the scientists, and not a fact upon which to found a patent.

The essence of Brush's broad invention was an improvement upon the secondary batteries of Planté, by adding the porous layer mechanically to the supports, in the manner described, instead of forming it by the tedious and inefficacious process of disintegration in the body of the plates themselves. When he is thoroughly protected in this invention he has received all that he is entitled to. By taking two patents he should not be permitted to multiply claims which could not stand side by side in one and the same patent.

There seems to be little controversy that *absorptive substance* and *active material* are used in the art as synonymous and equivalent terms, and have been so used since the time of Planté. The inventor, himself, apparently so understands it, for he has frequently used them interchangeably, not only in his testimony, but in the patent (Case J) itself.

Professor Barker says: "To a person skilled in the art, as it seems to me, the terms are only different forms of expression for one and the same thing. A secondary battery electrode, such as is contemplated in these patents, can consist of but two essential parts: (1) the material of the coating which gives to the battery its usefulness, and to which is due its capacity of storing electrical energy, and (2) the conducting frame or support upon which this material is spread. Since upon the former the action of the secondary battery depends, it has become the general practice to speak of it as the 'active material' of the electrode, in contradistinction to the support of the plate itself, which is or should be inert. The function of the coating is to change its chemical condition, as, for example, its state of oxidation, so far as to vary this condition in one direction in charging and in another on discharging. . . . Since, in my judgment, granular, porous or spongy lead, the substance of the first patent is 'active material or material adapted to become active' in the words of the second: and since the oxides of lead of the second patent 'are absorptive substances adapted to be transformed into an active coating' in the first, I am of the opinion that the 'absorptive substance' of the first patent and the 'active material' of the second are to be understood as equivalent terms." The Court is fully satisfied that this conclusion is correct.

The identity of the two patents can best be illustrated by placing similar claims in juxtaposition; the first claim of Case I, and the first and second claims of case J. for instance:

Case I.	Case J.
1. A suitable plate or support provided with mechanically-applied absorptive substance and adapted for use as a secondary battery element or electrode after being rendered active by an electric current, substantially as set forth.	1. A secondary battery element or electrode consisting of a plate or suitable support primarily coated or combined with mechanically-applied active material or material adapted to become active, substantially as set forth.
	2. In a secondary battery an electrode consisting of a plate or support provided with a coating or surface layer of an absorptive substance, such as metallic oxide, applied thereto, substantially as set forth.

There can be no question, if "absorptive substance" and "active material" are equivalent terms, that these claims are for the same invention. Each has the following elements: (1) A secondary battery support plate, (2) mechanically coated with (3) an absorptive or active material.

The question, then, is, Can a patentee who has received a patent for a plate coated with absorptive substance obtain another patent for the same plate coated with active material? Can an inventor obtain two patents for a broad invention because in one he practices the invention with one substance, and in the other he practices it with an equivalent substance? Manifestly not!

After Case I no one could have a patent for Case J, even if confined solely to the points wherein the two are said to differ. The former includes the latter. I am constrained to say, therefore, that the two patents are, in legal contemplation, the same. Although the possibility that the court might reach the conclusion was stated at the argument, neither counsel offered any solution of the difficulty and none has been offered since. The situation is certainly an unusual one. Here are two patents for the same invention applied for at the same time and granted at the same time. It is true that no injury can result in this particular instance, but what would be the situation if one of these patents were owned by a third party and a suit were brought on it against the defendants for the same infringement, or if the second patent were granted years after the first? If the principle is once established that an inventor can, by such inconsequential changes as here are shown, obtain two patents for the same invention, the greatest injuries may be done, both to competitors and to the public.

It would seem that the inventor had given Case I the preference; and as his expert regards that as as the broader of the two patents, the difficulty might be met by a surrender of Case J, or perhaps by a disclaimer of similar claims in Case J, leaving those which have not been brought into controversy or considered, and, possibly, the red lead claims, to stand. But, as neither counsel has expressed his views on this subject, the method of carrying out the opinion of the Court can best be arranged on the settlement of the decree.

Many of the propositions now advanced were examined and decided, upon identical testimony, by this Court, in the case of The Electrical Accumulator Co. *vs.* The Julien Electric Co. *et al.* 38 Fed. Rep., 117. These need not be again considered.

A definition of a secondary battery was there attempted and is now adopted for the purpose of this controversy. When the present inventor refers to a secondary battery he means precisely what Mr. Faure meant when he used that term.

It was further decided in the Accumulator case, that the exhibits which were the closest approximations to the invention were the article from the *Electrician* of 1863, the report of the Smithsonian Institution for 1856, the Grove gas battery, Planté's descriptions of 1872, and the patents to Kirchhof and Percival. Faure's claim, before being limited by a disclaimer, was broad enough to cover a secondary battery electrode to which the active material was applied, not only mechanically, but by galvanic action, chemical precipitation or in any other way, so that it was not formed out of the plates themselves in the manner described by Planté.

The evidence referred to, together with the testimony of Mr. Brush, was regarded as sufficient to limit the Faure invention to the application of the active material in the one form described by him, namely, as a paint, paste or cement. What effect the evidence disclosing the prior art had upon the patents in suit was, of course, not directly considered.

In the complainant's brief considerable space is devoted to the establishment of the proposition that Brush was, in legal contemplation at least, prior to Faure. It is thought that a discussion upon this point is unnecessary. The precise question was presented and decided in the interference proceedings before the Patent Office and in the Accumulator case. The defendant's counsel having there contended that Brush anticipated Faure, recognizes the impropriety of now contending that Faure anticipates Brush, and merely submits the testimony in this behalf without comment. The decision heretofore made upon the same state of facts will, therefore, be adhered to.

It was there decided—although the date was not definitely fixed—that Faure, being a citizen of France, and having received his invention in a foreign country, was not permitted to claim it here earlier than the date of the delivery of his French patent—Dec. 7, 1880. Faure's contributions to the art need not, therefore, be considered in this action.

The proof now offered to establish invention was carefully examined in the Accumulator case, and it was held that "the evidence of Mr. Brush as to what he accomplished in 1879 and 1880 must be accepted as true."

What did Brush accomplish?

A history of his experiments and their results is given at length in the other case (pages 129, 130, 131), and need not be again repeated. In brief, it is this: In the summer of 1879, he made secondary battery electrodes, by applying to suitable plates an active or absorptive coating consisting in three instances, respectively, of metallic lead in the form of a fine powder, red oxide of lead, and litharge. These coatings were held in place by a piece of blotting paper, a strip of wood and a string wound tightly around the whole. In July, 1880, he made lead plates with deep grooves; into the grooves of some he rammed yellow oxide of lead and in others sulphate of lead. In September, 1880, he made six plates grooved by a gang of circular saws, and filled the grooves of two by ramming them full of litharge, and of two others by ramming them full of sulphate of lead. The electrodes thus constructed operated successfully in secondary batteries and produced satisfactory results.

Many other structures leading up to the invention were made, but it is not necessary to consider them in detail. It may be said, however, that from the time the idea first entered his mind until the applications were filed, Mr. Brush was engaged, almost constantly, in progressive experiments and investigations.

For the reasons stated in the Accumulator case it is thought that this invention is not anticipated by the testimony of Professor Van der Weyde, the article from the *Electrician*, the Smithsonian report, the Grove battery, or the patents of Kirchhof or Pulvermacher (39 Fed. Rep., 490).

It was said of the patent granted to George C. Percival, April 3, 1866: The idea of Percival also, as shown in his United States Patent No. 53,668, was to improve on Planté's method by saving time and expense. He describes a secondary battery consisting of one pair of electrodes placed in a water-tight wooden box, divided in its centre by a porous partition. On each side of this partition is a layer of powdered gas carbon. These layers constitute the two electrodes, and when in use they are wet by a proper solution. For convenience in establishing connection with these layers there is on each end of the box a screw cup fastened to a strip of copper which is in contact with the carbon. "Lead or any other suitable metal in the form of a coarse powder may be substituted for the gas carbon. This appears to be somewhat analogous to some of the forms described by Faure. The complainant contends that the reference is valueless for the reason that there is no suggestion of a conducting support plate like Faure's, which holds the active layer and conducts electricity to each and all parts of it so that the whole material instantly becomes spongy and thus capable of receiving and discharging electricity. In short, that the Percival battery is without the Faure support plates." (Accumulator case, 38 Fed. Rep., 126.)

It is argued that this patent is an anticipation of claims 1 and 8 of Case I. This is probably true, if a very broad construction is placed on these claims, but there is nothing in the record requiring such a construction. There is no evidence that a Percival battery was ever used or could be made operative. His invention does not seem to be on the line subsequently followed by Brush. He has no plate or support at all resembling those of the Brush patents. He has no *coatings*. His two copper connecting slips *support* nothing. The pulverized gas carbon is not mechanically applied to them; they are simply in contact with the gas carbon. Their presence is not necessary; they are put there for greater convenience only. Percival's electrodes are not coated supports at all; they are cells filled with coarse conducting powder and divided by a porous partition.

Percival's claim is for:

"The forming of the electrodes of a secondary pile of layers of gas-carbon or some other conducting powder, substantially as, and for the purpose herein before described."

Is it not clear that he did not have in mind a lead, or other suitable plate with a layer or coating of active material mechanically applied thereto?

It would seem, then, that nothing in the record anticipates the Brush patent, Case I, when a construction commensurate with the invention is placed upon it.

He did not invent secondary batteries or electrodes for such batteries having a layer of active material, or the use therein of a conducting powder, but he seems to have been the first in this country who held the absorptive substance, in the form of dry powder, in place on the supports by paper or equivalent material, and the first who rammed or pressed it into grooves or receptacles in the plates.

The invention of Case I was not abandoned by descriptions in Patents No. 261,512 and 261,995, granted to Mr. Brush, respectively, July 18 and August 1, 1882.

There is no evidence as to when the applications for those patents were filed, other than the date appearing upon the specification, and this would seem to be insufficient proof of the fact. But accepting this date, June 9, as the true one, only four days elapsed before the filing of the application of Case I—June 13.

The inventor was not responsible for the delay in the Patent Office, which was occasioned by interminable interference proceedings between him and other inventors. His intention not to abandon is demonstrated by the fact that the application for the patent in suit was made out and sworn to two days before the application for the prior patents were filed.

In Holmes *vs.* Alarm Company, 33 Fed. Rep., 254, this Court decided that where a patent fully describes an invention which could be claimed therein, and makes no reservation and gives no warning to the public, a second patent granted upon an application filed months after the first patent was issued, which claims simply the invention previously made public, is invalid. But the Court also used the following language, which seems quite applicable here:

"This is not the case of a patentee who has made application for the second patent before the first is issued. It would be manifestly unfair to hold him responsible for the action of the Patent Office in this regard."

It is thought no authority can be found holding an invention abandoned upon such facts as are here developed. I should be sorry to make a precedent now which can have little but the most technical reasoning to support it.

The patent is not invalidated by the introduction of the descriptive term "absorptive substance" after the original application was filed. The claims as originally stated use the language "mechanically-applied porous, granular, spongy or equivalent lead." The claims as issued substitute the words, "mechanically-applied absorptive substance." This did not change the invention. It was the employment, simply, of more apt and artistic terms for the comparatively clumsy language of the original.

It is argued that claims 5 and 11 of Case I have been unlawfully expanded by the insertion of the word "perforations" therein. Neither the specifications, claims or drawing, as originally filed, mentioned perforations extending through the plate. They first appear in an amendment filed June 1, 1882.

Prior to this, in the summer of 1881, Professor Eaton had made perforated secondary battery plates. (Accumulator case, 38 Fed. Rep., 141.) John S. Sellon and Joseph Wilson Swan had described similar plates in their patents of March 10, 1882, and Nov. 22, 1881, respectively.

It is not contended that Mr. Brush ever made such a plate. There is no proof that he did, and he testifies that he cannot recall having done so.

The value of perforations extending through the plate seems to be conceded. Proof of the advantages of this construction appears in the record and the language of Sir William Thomson, who testified in the previous case, may be adopted as an epitome of what is affirmed by the witnesses here. (See Accumulator case, 38 Fed. Rep., 140.)

The complainant's brief contains the following:

"Thus perforations may, in his view, be a specific improvement over recesses or receptacles broadly considered, but recesses broadly considered in combination with the mechanically applied active or absorptive material in a secondary battery is the subject of the claims now under consideration." And again, "As to the improvement in recessed plates, which consisted in carrying the recesses through the plates and forming perforations, Mr. Brush has no separate claim for that specific improvement. Defendants insist that Swan has the prior right to that specific improvement. Brush's claims are for the broad ground of a recess, and it may be that Swan is entitled to be considered the first who carried the recess through the plates, making a recess which was also a perforation. But that question does not arise here."

But it seems that the question does arise. The claim is certainly susceptible of a construction covering a plate containing receptacles not only, but also perforations which go entirely through the plate. In other words, it may be construed to cover the features Mr. Brush is entitled to as well as the one he is not entitled to. So construed, an infringer, after paying complainant for the use of the recesses which belong to Brush, might also be compelled to pay for perforations which, so far as this patent is concerned, belonged to some one else—Eaton, Sellon or Swan. Neither of these gentlemen, if he had a patent for this specific improvement, could prevent complainant from using perforations as distinguished from recesses.

The common meaning of "perforation" is a hole or aperture through a body. It is argued that the patentee intended that this meaning should be adopted, for he says: "Fig. 8 shows a vertical section of a ribbed plate provided with slots or perforations extending through the plate." And yet, other parts of the specifications would indicate that he intended to make no distinction between perforations and receptacles. As before stated, the language quoted first appeared a year after the original application was filed. The Court has grave doubt, therefore, whether these facts do not bring the case within the rule laid down by Railway Co. *vs.* Sayles, 97 U. S., 563; Kittle *vs.* Hall, 29 Fed. Rep., 508, 514 and cases cited.

But consideration should be given to the unusual circumstance attending the filings of so large a number of applications and drawings at or about the same time. The inventor seems to have thought that by cross-references the information contained in all could be imported into each separately. This, certainly, bears upon the question of intent. The drawings which he afterwards filed in Case I were in fact filed with Case C, and were in the Patent Office when the application for Case I was filed. The third claim, as originally proposed, covered a ribbed, honeycombed or equivalent plate. If the claims as finally allowed may be fairly construed to cover nothing more than a honey-combed or equivalent plate, which certainly contemplates a plate containing cells or cavities, can it be said that the claims in question have been fatally expanded?

It is true that the ordinarily accepted meaning of the word "perforation" would imply an opening extending entirely through the plate, and such an opening the inventor could not engraft upon the original application. But the word may also have a meaning synonymous with "cavities" or "cells;" it may mean a hole not passing entirely through, but into the centre or interior, and a plate with such perforations the inventor was at liberty, it would seem, under the original application.

Such a construction does not interfere with the rights acquired by the public for it does not admit a broadening of the claim. It holds the inventor strictly to what he asked for in the first instance.

When, by a liberal construction, a patent may be sustained, is it not the duty of the Court to adopt it rather than one which, though possibly more plausible, will deprive the patentee of the fruits of a meritorious invention to which he is fairly entitled?

With considerable hesitation I shall hold that these claims, as thus construed, are valid. That they are infringed there can be little doubt. The defendants' electrodes have receptacles; they may be improved receptacles, but they are receptacles nevertheless. These claims do not cover the improvement.

Regarding the pressure claims, so called, the defenses are that they are void for want of intention, and if a construction is placed upon them sufficiently narrow to enable them to stand, the defendants do not infringe.

The tenth claim of 337,298 is as follows:

"10. In the process of making a secondary battery plate or element combining, by means of pressure, an absorptive substance and suitable material to form a support therefor, substantially as set forth."

The only claim of No. 260,654 is as follows:

"The method of forming the plates of a secondary battery, consisting in forming receptacles for oxides of lead in its surface then applying oxide of lead to the plate and within such receptacles, and afterward subjecting the oxides of lead to pressure."

The latter is a narrower claim than the former, being limited to oxides of lead, to support plates having receptacles and to pressure after, and, therefore, in addition to, the mere mechanical application.

It is not denied that the prior art plainly reveals the use of pressure in making primary battery plates. The distinguishing feature of the invention of these claims is *pressure*. Every other element is covered by other claims. It is argued with plausibility and force that it is not invention for the patentee, with the coated plate before him, to subject it to treatment which he could easily have learned from Laclanché and others.

It is said that the function of pressure is the same whether used on a primary or secondary battery electrode, and that the claim cannot be upheld by importing into it all the valuable features of the broad invention.

It is contended for the complainant, on the other hand, that pressure applied to secondary battery plates produces an entirely different result and performs an entirely different function from that produced when applied to primary battery plates.

If the claims are limited to the use of hydraulic, or other similar pressure, the Court, as now advised, would be inclined to recognize the force of the complainant's contention.

But the construction asked for is broad enough to cover the application of the absorptive material with trowel or spatula and the incidental pressure attending this operation.

Says the complainant's expert: "In the plates of defendants' battery I find a series of small cells perfectly filled with an apparently uniform and extremely even mass of absorptive material. I know of no way in which this could have been effectively done except by spreading and forcing into the perforations the absorptive substance, either in the form of a paste or of a powder; generally the application of the absorptive substance to the plate is accomplished by means of a trowel or spatula; the support is usually laid upon a slab or some material such as slate or glass, and the absorptive material, in the form of powder or paste, is spread over the plate and forced into the perforations; considerable pressure is always applied to the material to force it into the receptacles; the excess of material is removed by a spatula or some equivalent implement, and the plates are then quite smooth, the absorptive material at the receptacles having almost the thickness of the support plate. From a careful examination of defendant's batteries and from my general knowledge as to the methods employed, I am of the opinion that the absorptive material has been applied in substantially the manner of the tenth claim above described, and that considerable pressure has been employed in the operation."

There can be no doubt that a construction as broad as here demanded would invalidate the claim. It would cover a well known and exceedingly simple operation. It would cover the mechanical application of the coating. It is hard to conceive how it could be made to adhere without some degree of pressure. Even the blotting paper, stick and string of the 1879 electrode would infringe. Pressure such as this, it is believed, was not contemplated by the inventor. He had in view pressure, plus the chemical application, by means of which the coating would adhere more perfectly not only, but by which better conductivity could be obtained.

But if the narrower construction is given these claims, the defendants do not infringe; at least they have not been proved infringers.

I do not lose sight of Mr. Weston's later testimony taken April 8, 1889, but it seems to me that it adds nothing to his former statements upon which the Court would be warranted in acting. It is hearsay merely and wholly indefinite as to time. The bill was filed in April, 1887, alleging that before the commencement of the action the defendants had infringed. This allegation is hardly sustained by the testimony of a witness taken two years later that he has been informed that the defendants have infringed for "some time."

The stipulation signed by the defendants' solicitors, designed to cover undisputed matters upon the subject of infringement, makes no mention of pressure.

Case C, No. 266,090, contains two classes of claims. The first class (claims 1 to 8 inclusive) relates to the form of the plates; the second class (claims 9, 12 and 14) to the material of which the plates are formed.

Claim 7 relates to a secondary battery electrode having its support provided with "cells or cavities;" other claims of the first class relate to "ribs."

Claim 14, in addition to the element of cast-lead, has also the element, not elsewhere claimed in this patent, of "slots, perforations or openings."

It is said that the defendants do not infringe the claims of the first class, other than the seventh, for the reason that they do not have a ribbed support plate. The language of the seventh claim described with much greater precision the defendants' supports than that of any other claim of this class. They certainly use cells or cavities. Whether they use ribs or not is, at least, doubtful.

If there were nothing in the art but the contributions of Mr. Brush, it is evident that a narrow construction must be given to these claims. Every word by which even a shade of distinction in the formation of these plates can be expressed, has been adopted. Advantages of the most surprising and mysterious character are said to lurk in the slightest change of size, shape or depth in the holes or recesses. In these circumstances a different rule should be adopted than if the art showed that all these methods of keeping the active material in place are, substantially, equivalent.

The defendants use a support filled with rows of uniform square holes. The Court is not prepared to say that the walls between these holes are ribs. The ordinary meaning of the word would have to be strained and distorted to make it cover "partitions or septs between the cavities," and especially so in an art where a restricted meaning is required. A careful reading of the specification confirms the impression that the patentee intended to use the word, not as now asserted, but in its ordinary sense, as synonomous with projections or ridges. He intended to draw, and does draw, a sharp distinction between plates with ribs and those with cells, cavities and perforations.

Claims 9 and 12 are clearly void for want of patentable novelty. Their only distinguishing feature is cast-lead. The complainant, if its position is correctly understood, does not assert that there is anything patentable in casting lead. It is not alleged that the eleventh claim, which covers the process of casting, is infringed. Not only every skilled mechanics but every schoolboy who has experimented with melted lead, who was shown a model of defendants' grid, and asked to make a series of them, would at once suggest the idea of casting them in molds. This proposition is, virtually, conceded by the complainant's counsel, for in speaking of the advantages of casting over rolling or pressing, they say: "If this latter were the only advantage and the only mode of operation and result then the invention would be old in any casting of a complex form, and that is the plane on which defendants deal with this invention; but the true understanding of the invention shows that it had its birth in the needs of secondary batteries that operate by expansion and contraction of a permanent coating which must be allowed to get away from its support, and that its peculiar mode of operation and advantages exist only in such a battery."

What, then, is the novelty upon which these claims are sought to be sustained? It would seem to rest solely on the theory that cast-lead produces better results on a secondary battery than rolled or pressed lead. A patent cannot stand for a moment upon ground so narrow. Lead plates were old in secondary batteries, cast-lead plates were old in primary batteries. The art of casting was old and free to all. The form of the plates desired would suggest casting them to the skilled artisan. This right being clear, it is idle to assert that one may cast his plates, but shall not be permitted to use them after they are cast. It being quite impossible to pour melted lead into molds without producing cast-lead the question arises: Can the person who first uses the obvious process in making secondary battery plates not only obtain a monopoly of the product but of the process as well? Manifestly not! It is not even the substitution of one known material for another. It is the substitution of one well known form for another well known form of the same material.

In Hotchkiss *vs.* Greenwood, 11 How., 243, the Court says: "The improvement consists in the superiority of material, and which is not new, over that previously employed in making the knob. But this, of itself, can never be the subject of a patent. No one will pretend that a machine, made in whole or in part, of materials better adapted to the purpose for which it is used than the materials of which the old one is constructed, and for that reason better and cheaper, can be distinguished from the old one, or, in the sense of the patent law, can entitle the manufacturer to a patent. The difference is formal, and destitute of ingenuity or invention. It may afford evidence of judgment and skill in the selection and adaptation of the materials in the manufacture of the instrument for the purpose intended, but for nothing more."

See also Bushing Co. *vs.* Doelger, 23 Blatchf., 167, and cases cited.

With every disposition to act with liberality toward those who, with undoubted genius and untiring research, are developing this recently discovered mine of industry, the Court cannot ignore the repeated and uniform utterances of the Supreme Court upon the subject:

In addition to the familiar and oft quoted authorities, see the following decided at the present term:

Burt *vs.* Evory, Feb. 3, 1890; Hill *vs.* Wooster, Jan. 13, 1890; Day *vs.* Railway Co., 132 U. S., 98; Watson *vs.* Railway Co., Id. 161; Marchand *vs.* Emken, Id. 195; Royer *vs.* Roth, Id. 201.

Claim 14 may be construed as covering a combination, one element of which, the slots, etc., is new and useful, and is not covered by the other claims. The original specification and drawings, filed June 9, 1881, describe and show grooved, honey-combed and slotted plates. Indeed, the drawings, for the absence of which Case I is criticized, were filed at the outset in case C.

"Of Fig. 4, showing the slotted plate the specification say:

"Here the supporting plate between the ribs is removed, the latter being supported by the heavier side or end ribs and other intermediate transverse ribs if necessary. This modification is in form somewhat like an ordinary window blind with the slats open."

This can mean nothing else except that there were openings extending entirely through the plate. The specification as originally filed is sufficient, therefore, to support the claim, Regarding the infringement of this claim and claim 7 there can be no doubt, and the same is true of the claims in controversy of Case I.

The point is suggested that the defendant Bracken is not proved to be an infringer, but the stipulations signed by the solicitors makes no distinction between the defendants.

The questions arising on the expiration of the Italian patent are of a serious character, and, in view of the elaborate attention given to the other defenses, would seem to demand greater consideration in the testimony and in the briefs. The patent appears in the record, but no word of explanation, so far as can be discovered, has been offered on the part of the defendants. The only testimony explanatory of the patent is the clear and positive statement of the complainant's expert, that it describes and claims inventions entirely different from those of the patents in controversy.

The patent contains five divisions and twenty-two claims. It requires but little expert knowledge to perceive that some of these are wholly dissimilar to the inventions in suit. Others would seem to be dangerously near to some of the inventions, but those portions of the Italian patent, which seem to the Court to be most in point are but little discussed, and in some instances are not even alluded to in the defendants' brief.

For example, take a portion of Division D and its corresponding claims. The Italian patent says:

"To form an element having a core or body coated with the mass described, I take a sheet or other suitable piece of lead, or of other substance suitable for the purpose, and if necessary roughen or score its surface, or pierce it with numerous perforations to insure a firm adhesion of the mass which is to constitute the active coating. I cover it with the finely divided superficially oxidized lead (or the mixture of metallic lead and lead oxide particles) and apply heavy pressure. The result is that the finely divided particles are not only pressed into a firm and strongly coherent mass, but the mass is also firmly united to the supporting core or body. This core may be of lead, or it may consist of non-oxidizable metal, such as gold or platinum, or any alloy of these metals with lead."

Claim 17 of the Italian patent is as follows:

"A process for making secondary battery elements (or material from which said elements can be constructed); said process consisting in covering one, or more, or all of the surfaces of a suitable metallic or electro-conducting core or body, either with superficially oxidized particles of lead, or with a mixture of particles of pure lead and lead oxide, and, afterward, applying pressure sufficient both to unite said particles or mixture into a compact and firmly coherent mass, and to unite the mass to the core or body, as set forth in 'Division D.'"

Bearing in mind the fact that metallic lead and lead oxide are absorptive or active material, a comparison with some of the claims in controversy will certainly show marked features of similarity.

Claim 10 of Case I is as follows:

"In the process of making a secondary battery plate or element, combining by means of pressure an absorptive substance and suitable material to form a support therefor, substantially as set forth."

To the uninitiated it would seem that these claims are for similar inventions. Would not a person, following the formula of the Italian patent, infringe the pressure claims of the patent in suit? Is not the method of making electrodes by pressing active material upon the support set free "by the expiration of the Italian patent?"

It is also true that Division D of the Italian patent describes also the process of uniting the absorptive substance into a compact or firmly adherent body or mass without the intervention of a support plate, but to the ordinary reader it would seem to be reasonably clear that when the inventor says, as in the description quoted, that he takes a sheet of lead, pierces it with numerous perforations to insure a firm adhesion of the mass which is to constitute the active coating, covers the support with the mixture of metallic lead and applies heavy pressure, so that the mass is not only pressed together but is also firmly united to the supporting core, he is describing the process which is covered by the claim in question.

Other claims of the Italian patent are as follows:

"11. As a new article of manufacture, a mass consisting of a mechanical mixture or association of metallic lead and oxide of lead, united by pressure into a coherent and firm body, substantially as set forth in 'Division D.'

"14. For use in an element of a secondary battery, a metallic core, or body, to one or more sides of which is attached a mass or substance, primarily consisting of metallic lead or oxide of lead, united by pressure so as to be strong and firmly coherent, substantially as set forth in 'Division D.'

"15. A secondary battery element, consisting of a metallic core, or body having attached to it a coating primarily consisting of mixed lead and oxide of lead, firmly united by pressure into a strong and coherent mass, substantially as set forth in 'Division D.'

"16. A secondary battery element, consisting of the combination with a metallic supporting core or body of a coating attached or united to said core; said coating primarily consisting of metal-lead and lead oxide in an intimately commingled state, united by pressure into a strong and firmly coherent mass, substantially as set forth in 'Division D.'"

It will be observed that the first of these, Claim 11, covers only lead and oxide of lead mixed and united by pressure into a coherent mass for use as an electrode or as a coating. The element of a support plate is wanting in this claim, but it is present under the name of "a metallic core or body," in all the others.

Compare these claims with the pressure claims of the patents in suit, but also compare them—and particularly claim 11—with claims 12 and 13 of Case I. They are as follows:

"12. Absorptive material for use in secondary batteries formed into a coherent mass by pressure, substantially as set forth.

"13. For use in secondary batteries, porous, granular, spongy, or equivalent lead formed into a coherent mass by pressure, substantially as set forth."

The language is different, but in substance where is the lack of identity?

But all these are questions which the Court, in view of the action of the American and Italian patent officials, in distinguishing between the inventions covered by the Italian patent and those covered by the patent in suit, and in view of the uncontradicted opinion of the complainant's expert, should hesitate long before answering in the affirmative.

Mr. Weston says of "Division D" of the Italian patent:

"It is for an improved form of electrode especially adapted to the foundation by electrical disintegration either by the Planté method or by the peculiar method of electrical disintegration invented by Mr. Brush and described in Division A."

It should be remembered that we are dealing here with a mysterious and occult power of nature, the science of which is still in its infancy, the phenomena of which are but little understood, even by those who have made its study their life work. For one who has but a casual and superficial knowledge to place a construction upon a patent, which is addressed to those who are educated in this department of science, and which constantly employs terms of art, in opposition to the opinion of the only electrician who speaks upon the subject, would be unwarranted especially when such a construction will destroy rights an interests of great value. In very many of the patent causes which come before the courts, where the device is so simple that any man of ordinary capacity can understand it, the presence of an expert is wholly unnecessary, but when the invention relates to a subject where even the pioneers are still groping in shadows, the Court needs the instruction of those most competent to advise, and without such assistance should proceed with the utmost caution. The law does not favor forfeitures. A patent should never be declared invalid because of the expiration of a foreign patent, if there is doubt about the inventions being the same. The burden is upon the defendants and the doubt should be resolved in favor of the patent.

After such study as I have been able to give the subject, I am not satisfied that the Italian patent is for the same invention as those in controversy. It is sufficient, for present purposes, to state that the mind of the Court is in doubt upon the question.

The language of Judge Bradley in the case of Bishof *vs.* Wethered, 9 Wall, 312, where a patent was introduced, as here, without explanation, seems particularly applicable.

"The specifications of patents for inventions are documents of a peculiar kind. They profess to describe mechanisms and complicated machinery, chemical compositions and other manufactured products, which have their existence *in pais*, outside of the documents themselves; and which are commonly described by terms of the art or mystery to which they respectively belong; and these descriptions and terms of art often require peculiar knowledge and education to understand them aright; and slight verbal variations, scarcely noticeable to a common reader, would be detected by an expert in the art, indicating an important variation in the invention. Indeed the whole subject matter of a patent is an embodied conception outside of the patent itself, which, to the mind of those expert in the art, stands out in clear and distinct relief, while it is often unperceived, or but dimly perceived by the uninitiated. This outward embodiment of the terms contained in the patent is the thing invented, and is to be properly sought, like the explanation of all latent ambiguities arising from the description of external things, by evidence *in pais*." It was, therefore, decided that the Circuit Court was right in charging the jury that there was not on the face of the respective patents such an identity as authorized the Court to pronounce that they were for the one and the same invention.

No. 260,654 is not, in any event, affected by the Italian patent. The former bears date July 4, 1882, the latter Aug. 8, 1882, and it was not applied for until July 28, 1882.

It follows that upon filing a disclaimer of the invalid claims the complainant is entitled to a decree in accordance with this opinion, but without costs.

In connection with this decision the following statement should, I think, be made:

A suit similar to this is pending against the Electrical Accumulator Company. Sometime after the oral argument in this cause was concluded, the counsel for that company, after due motion to all parties interested, called the attention of the Court to the following facts:

On the 28th of March, ten days after the decision on the Faure patent was filed, the president and secretary of the Julien Company, without the knowledge or consent of counsel, obtained from the complainant an option to take an exclusive license under the patents in suit provided they were sustained.

In view of these facts the Court was asked either to refuse to decide the case altogether or to postpone the decision until the cause against the Accumulator Company is ready for argument.

The Court urged upon counsel the importance of having the issues passed upon in a controversy which is, in all respects, genuine and earnest, and expressed his own disinclination to decide an action where a suspicion to the contrary might exist. Several plans were suggested, but none upon which counsel could agree. As the option alluded to is not regarded as a settlement of the cause, the conclusion has been reached that justice to the parties demands that a decision should be made at this time.

I regret having to inflict so long an opinion upon litigants and counsel, but the examination and study of a record and briefs aggregating twenty-five hundred printed pages, has made it impossible to devote the necessary time to review and condensation.

AN IMPORTANT DECISION BY THE UNITED STATES SUPREME COURT.

POHL VS. ANCHOR BREWING CO.

On Monday, March 24th, the United States Supreme Court handed down its decision in the case of Pohl *vs.* Anchor Brewing Co., which involves a most vital point in connection with American patents for which foreign patents have also been issued. As our readers are aware, section 4,887 of the Revised Statutes limits the life of the United States patent to the shortest term of the prior foreign patent. Hence the lapse of such a foreign patent, through whatever cause, has heretofore been held to terminate the life of the United States patent, and this view was taken by Judge Wallace in the above case. His decision has, however, been reversed by the Supreme Court in an opinion written by Judge Blatchford. After reciting the pleadings and discussing the case the Court says:

"We think that the question involved in the present case is not the same as that decided in Bate Refrigerating Co. *vs.* Hammond, and is not controlled by the decision in that case. There a United States patent was granted in November, 1877, for seventeen years. A patent for the same invention had been granted in Canada to the same patentee for five years from January, 1877. The Canadian patent was, in December, 1881, extended for five years from January, 1882, and also for five years from January, 1887, under a Canadian statute passed in 1872. The question involved was whether, under section 4,887, the United States patent expired in January, 1882, or in January, 1892. This Court, limiting itself to the precise question involved, said that it was "of opinion that, in the present case, where the Canadian statute under which the extensions of the Canadian patent were granted was in force when the United States patent was issued, and also when that patent was applied for, and where, by the Canadian statute, the extension of the patent for Canada was a matter entirely of right, at the option of the patentee, on his payment of a required fee, and where the fifteen years' term of the Canadian patent has been continuous and without interruption, the United States patent does not expire before the end of the fifteen years' duration of the Canadian patent."

This was said on the view, expressed elsewhere in the opinion, that the Canadian patent did not expire, and it never could have been said properly that it would expire, before January, 1892. The ground of this conclusion was, that the "term" of the Canadian patent granted in January, 1877, was by the Canadian statute at all times a term of fifteen years' duration, made continuous and uninterrupted by the action of the patentee, as a matter entirely of right, at his own option.

"By parity of reasoning, as applied to the present case, section 4,887 requires that the United States patent shall be so limited as to expire at the same time with the term limited by the foreign patent issued prior to the issuing of the United States patent, having then the shortest time to run. There is nothing in the statute which admits of the view that the duration of the United States patent is to be limited by anything but the duration of the legal term of the foreign patent in force at the time of the issuing of the United States patent, or that it is to be limited by any lapsing or forfeiture of any portion of the term of such foreign patent, by means of the operation of a condition subsequent, according to the foreign statute. In saying that 'every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent,' the statute manifestly assumes that the patent previously granted in a foreign country is one granted for a definite term; and its meaning is, that the United States patent shall be so limited as to expire at the same time with such term of the foreign patent. Such term was held, in Bate Refrigerating Co. *vs.* Hammond to be fifteen years and not five years.

"This view is made conclusive by the requirement of section 4,887, that if there be more than one prior foreign patent, the United States patent shall be so limited as to expire at the same time with that one of such foreign patents 'having the shortest term.' This means the foreign patent which, at the time the United States patent is granted, has then the shortest term to run, irrespective of the fact that the foreign patent may afterwards lapse or become forfeited by the non-observance of a condition subsequently prescribed by the foreign statute.

"In the view that section 4,887 is to be read as if it said that the United States patent is to be so limited as to expire at the same time with the expiration of the term of the foreign patent, or if there be more than one, at the same time with the expiration of the term of the one having the shortest term, the interpretation we have given to it is in harmony with the interpretation of the words 'expiration of term' in analogus cases. (Oakley *vs.* Schoonmaker, 15 Wendell, 226; Beach *vs.* Nixon, 9 N. Y., 35; Farnum *vs.* Platt, 8 Pick., 338.) In those cases it was held that the words 'expiration of term' do not mean expiration of term through a forfeiture by breach of a condition, but mean expiration by lapse of time.

"The decree of the Circuit Court is reversed, and the case is remanded to that court with the direction to overrule, with costs, the plea of the defendant, to assign it to answer the bill, and to take such further proceedings as shall not be inconsistent with the opinion of this Court."

This case is one which has been watched with considerable interest by the electrical fraternity, as in one of the suits between the Edison Co. and the United States Electric Lighting Co. a similar plea had been entered to prove the invalidity of the main Edison lamp patent.

The reversal of Judge Wallace's decision gives the American inventor the right to his patent up to the term for which the foreign patent was originally granted, independent of any subsequent causes by which it may have been allowed to lapse abroad.

THE suit which was brought by the Edison Electric Light Company against Westinghouse, Church, Kerr & Company, in 1886, alleging infringement of Edison's patent No. 274,290, for the plan of electrical distribution known as the "three-wire" system, was heard in the United States Circuit Court, at Trenton, New Jersey, on May 10, 1889. Nearly a year has elapsed, but no decision has yet been handed in. The plant at Trenton, which was alleged to contain the infringement was changed over to the alternating system some two years ago, so that the decision when rendered will be of importance mainly as defining the validity and scope of the three-wire patent.

Another suit brought by the Edison company in 1886, against the same defendants, alleging infringement of Edison's patent No. 264,642, commonly known as the "feeder and main system" is still in progress. The complainants have closed their *prima facie* case and the defendants have just commenced taking testimony for the defence.

The suit of the Consolidated Electric Light Co. *vs.* the Edison Electric Light Co., alleging infringement of Sawyer & Man's patent of June 5, 1878, for the method of connecting electric lamps in multiple series, is still in progress. The complainant's *prima facie* case has been closed, and the expert testimony in behalf of the defendants is now being taken.

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

From February 18 to March 25 (inclusive.)

Alarms and Signals:—*Annunciator*, T. H. Shipway and J. R. Dowdell, 421,439. *Electrical Annunciator*, A. F. Parks, 421,508. *Time-Alarm*, G. H. Straight, 421,530. *Electric Railway Signal*, W. C. Walter, 421,791. *Automatic Fire-Alarm System*, G. F. Bulem, 421,853. *Automatic Fire-Alarm Transmitter*, same, 421,854. *Visual Annunciator for Call-Boxes*, P. Seiler, 421,882, February 18. *Automatic Railway Alarm and Signal*, M. M. Souders, 421,983, February 25. *Electric Time-Alarm and Annunciator*, N. H. Suren, 422,654. *Electro-Magnetic Annunciator*, C. J. Hamilton, 422,778. *Low Water Alarm for Steam Boilers*, E. E. Kildoyle, 422,803, March 4. *Automatic Electrical Annunciator*, B. F. Shafer, 422,981, March 11. *Annunciator*, C. E. Scribner, 423,494. *Bell*, L. M. Linolet, 423,637. *Electric Bell*, A. F. Stanley, 423,707. *Electric Burglar and Fire Alarm*, W. Gee, 423,758, March 18. *Electric Alarm for Letter-Boxes*, W. G. Reed, 424,219. *Burglar Alarm*, N. M. Watson, 424,387. *Municipal Signaling Box*, F. Pearce, 424,431, March 25.

Clocks:—*Electro-Magnetic Watch-Clock*, R. B. Carr, 424,268. *Electric Time Dial*, C. A. Colby and J. C. Strong, 424,273, March 25.

Conductors, Insulators and Conduits:—*Conduit for Electric Railways*, P. H. Griffin, 421,398. *Electric Conductor*, J. A. Stoughton, 421,781. *Insu-*

lator, J. W. Davy, 421,819, February 18. *Electric Conductor*, E. F. Phillips, 421,968. *Electric Connector*, C. McIntire, 422,058. *Device for Suspending Electric Conductors at Crossings*, S. H. Short, 422,096. *Support for Overhead Electric Conductors*, C. K. Stearns and G. K. Wheeler, 422,164, February 25. *Compound Insulating Layer for Electric Coils*, E. Thomson, 422,550. *Insulator*, G. E. Stanley, 422,651, March 4. *Underground Electric Conduit*, A. Bruner, 423,023. *Laying Electric Conductors*, T. J. Cope, 423,134, March 11. *Crossing for Electric Conductors*, H. A. Seymour, 423,495. *Electrical Conductor*, G. E. Miller, 423,527, March 18. *Underground Conduit for Electric Wires or Cables*, C. G. Gilman, 424,057, March 25.

Distribution:—*Electrical Induction Apparatus or Transformer*, M. Von Dolivo-Dobrowolsky, 422,746, March 4. *Isolated System of Electric Lighting*, J. F. McLaughlin, 424,339, March 25.

Dynamos and Motors:—*Dynamo-Electric Machine*, DeW. B. Brace, 421,479. *Electric Motor*, P. B. Walsh, 421,790, February 18. *Regulating Apparatus for Electric Motors*, P. Diehl, 421,911. *Dynamo-Electric Machine*, M. Pfatischer, 421,967. *Dynamo-Electric Machine or Electric Motor*, E. B. Parkhurst, 422,148. *Electric Motor*, same, 422,149. *Carbon Commutator-Brush and Holder*, C. J. Van Depoele, 422,265. *Pyromagnetic Generator and Motor*, W. B. Cooper, 422,295, February 25. *Armature*, C. D. Jenney, 422,419 *Dynamo-Electric Machine*, R. Eickemeyer, 422,511. *Electric Motor*, H. E. Walter, 422,556. *Armature for Electric Machines*, J. C. Wray, 422,681. *Pulsating Electric Generator*, C. J. Van Depoele, 422,855. *Pulsatory Current Motor*, same, 422,856. *Alternate-Current Pulsating System*, same, 422,857. *Converting Continuous into Pulsating Electric Currents*, same, 422,858. *Pulsating Current System*, same, 422,859. *Multiple-Current Pulsating Generator*, same, 422,860. *Regulating Electric Motors*, G. A. Washburn, 422,862. *Armature for Dynamos*, etc., same, 422,863, March 4. *Electromotor*, H. R. Butterfield, 422,911. *Field Magnet for Dynamos*, E. Thomson and A. L. Rohrer, 422,999. *Armature*, R. L. Cohen, 423,026. *Regulation of Alternate Current Generators*, S. C. C. Currie, 423,029. *Holder for Commutator Brushes*, J. C. Chamberlain, 423,309, March 11. *Alternating Current Electric Regulator*, L. Gutmann, 423,553, March 18. *Constant Current Motor*, W. Baxter, Jr., 423,897. *Regulator for Dynamos*, H. W. Cooley, 423,909. *Commutator Brush*, P. Diehl, 423,912. *Controller for Electric Motors*, M. J. Wightman, 423,975. *Dynamo-Electric Machine*, S. Z. De Ferranti, 423,991. *Commutator*, W. F. D. Crane, 424,406. *Electro-Magnetic Motor*, N. Tesla, 424,036. *Dynamo-Electric Machines*, C. D. Jenney, 424,065, March 25.

Galvanic Batteries:—*Electric Battery*, C. Wilms and G. A. Liebig, Jr., 421,801, February 18. *Automatic Switch for Regulating the Power of Electric Batteries*, G. B. Pennock, 422,438. *Galvanic Battery*, J. H. Linville, 422,534, March 4. *Zinc Electrode for Galvanic Batteries*, G. d'Infreville, 422,925. *Dry Galvanic Battery*, L. Moorthamers, 434,335, March 11. *Galvanic Battery*, M. M. Clark, 423,594, March 18.

Lamps and Appurtenances:—*Arc Light Carbon*, W. E. Adeney and L. Saunderson, 421,469. *Camera and Electrical Flash Light Attachment*, G. E. Davis, 421,484. *Incandescent Lamp Socket*, W. P. Kookogey, 421,586. *Electric Lamp Adapter*, J. Stewart, 421,630. *Carbon for Arc Lamps*, E. L. Liedke, 421,733. *Hanging Device for Electric Lamps*, W. H. Layng, 421,864, February 18 *Exhaust Apparatus for Incandescent Lamp Globes*, H. J. Jaeger, 422,219. *Carbon for Electric Lamps*, H. H. Head and L. Saunderson, 422,302. *Safety Cut-Out*, F. B. Rae, 422,351. *Incandescent Lamp Socket*, W. F. Wollin and E. H. Werline, 422,360, February 25. *Arc Lamp*, G. C. Pyle, 422,446. *Carbon for Electric Lamps*, W. F. Smith, 422,456. *Incandescent Gas Lamp*, J. N. Pew, 422.536. *Suspension Device for Incandescent Lamps*, H. W. Hayden and C. S. Dikeman, 422,591. *Reflector for Incandescent Lamps*, F. Holman, 422,592. *Incandescent Lamp Socket*, F. C. Rockwell, 422,684. *Lighting Fixture*, P. C. J. Lemaire, 422,811. *Manufacture of Carbons for Electric Lamps*, W. F. Smith, 422,895, March 4. *System of Arc and Incandescent Electric Lighting*, H. P. Brown, 422,910. *Portable Electric Lamp*, A. H. Bauer, 423,207, March 11. *Carbon Rod for Arc Lamps*, C. E. Scribner, 423,637. *Cut-Out for Electric Arc Lamps*, same, 423,638. *Arc Lamp*, H. Pieper, Fils, 423,807, March 18.

Measurement:—*Electrical Indicator*, L. Bock, Jr., 421,851, February 18. *Galvanometer*, J. Waring, 422,672, March 4. *Electric Meter for Alternating Currents*, O. T. Blathy, 423,210, March 11. *Ampere Meter*, G. A. Frei, 423,600, March 18. *Electric Meter*, W. McKinney, 424,338. W. J. Bagby, 424,401, March 25.

Medical and Surgical:—*Electric Belt*, M. Wadleigh, 421,457, February 18. *Voltaic Shoe*, C. H. Ayer, 422,107, February 25. *Apparatus for Medicating, Compressing and Administering Air*, J. C. Kennedy, 422,802, March 4. *Electro-Therapeutic Appliance*, C. E. Brunning, 423,549. *Galvanic Apparatus for Dental Surgery*, C. Wm. Manker and G. F. Manker, 423,616. *Electrical Device for Use in Dental Operations*, same, 423,617, March 18. *Therapeutic Galvanic Apparatus*, T. Schmauser, 423,959. *Electro-Medical Chair*, M. A. MacMaster, 424,012, March 25.

Metallurgical:—Furnace, G. P. Denis, 422,189, February 25. *Magnetic Separator*, G. Conkling, 422,732, March 4. *Process of Electro Plating Non-Metallic Articles*, W. H. Winslow, 423,101, March 11. *Process of Separating Magnetic Particles*, G. Conkling, 423,907, March 25.

Metal Working:—*Method of Electrically Heating Bars, etc., for Welding and Working Purposes*, M. W. Dewey, 422,190, February 25. *Method of Electric Welding*, C. L. Coffin, 422,730, March 4. *Method of Welding Metals by Electricity*, same, 423,732, March 18. *Method of and Apparatus for Electric Welding*, same, 423,733. *Method of Welding Metals by Electricity*, same, 423,734 and 423,735. *Method of Welding Metals Electrically*, same, 423,736, March 18. *Method of Manufacturing Projectiles by Electric Welding*, W. M. Wood, 424,441. *Electric Forging Machine*, R. Ross, 423,956. *Method of Electric Soldering, Cementing*, etc., E. Thomson, 423,966. *Apparatus for Electric Soldering and Cementing*, same, 423,967, March 25.

Miscellaneous:—*Cut-Out*, G. A. Frei, 421,396. *Electro-Magnetic Valve Controller*, J. V. Stout, 421,449. *Apparatus for Heating Water and Generating Steam by Electricity*, same, 421,499. *Electric Lock*, W. Grah, Jr., 421,567. *Thermostat*, G. F. Bulem, 421,852, February 18. *Electric Switch*, W. E. Parker and H. E. Temple, 422,147. *Electric Lighting Device*, E. E. Flora and P. R. Hoy, 422,196. *Electrical Apparatus for Driving Artesian Wells*, G. G. Freyer, 422,201. *Electrically Propelled Vehicle*, J. Adair, 421,887, February 25. *Coin-Controlled Weighing and Strength-Testing Machine*, J. F. Bower, 422,876. *Inductorium*, A. H. Hoyt, 422,885. *Electro-Magnet*, R. Eickemeyer, 422,512. *Automatic Circuit Breaker*, M. C. Happoldt, 422,524, March 4. *System for Stopping Machines*, W. H. Kilbourn, 422,948. *Electric Valve Controller*, E. R. Malmborg, 422,956. *Electrically Controlled Elevator*, W. J. Paine, 422,968. *Casing for Electric or Other Apparatus*, L. S. Woodbury, 423,014. *Phonograph for Dolls or Other Toys*, T. A. Edison, 423,039. *Thermal Cut-Out*, J. J. Wood, 423,102. *Electric Heating Apparatus*, M. W. Dewey, 423,223. *Electric Shaft Controller*, A. W. Hart, 423,245. *Stationary Fire-Extinguishing Apparatus*, W. C. Smith, 423,286. *Coin Operated Electric Apparatus*, J. S. Wallace, 423,361. *Self-Destructive Torpedo Vessel*, S. Barton, 423,405, March 11. *Apparatus for Producing Steam, Heat and Light by Electricity*, T. D. Farrall, 423,421. *Electric Wire Molding*, J. A. Seely, 424,449. *Electric Switch*, G. H. Whittingham, 423,462. T. F. McEvoy, 423,488. *Coin Operated Display Apparatus*, E. H. Amet, 423,654. *Static Electrical Machine*, H. Tirmann, 423,708. *Lightning Arrester*, G. S. Maxwell, 423,788. *Switch for Electric Apparatus*, S. L. Barriett, 423,891, March 18, *Electric Valve Controller*, E. Thomson, 423,965. *Igniting Apparatus for Gas Engines*, E. F. Roberts, 424,027. *Electric Radiator*, H. R. Butterfield, 424,047. *Circuit-Closer*, J. A. Dempf, 424,182. *Thermostat*, W. F. Singer, 424,363. *Electric Stop-Motion for Knitting Machines*, J. P. Haslam, 424,295. *Electric Heating and Cooking Device*, H. R. Butterfield, 424,403. *Electric Flat Iron*, H. R. Butterfield and W. Mitchell, 424,404, March 25.

Railways and Appliances:-*Electric Railway Car*, H. C. Wirt, 421,464. *Switch for Systems of Electric Locomotion*, F. Wheeler, 421,535. *Support for Trolley Wires*, J. H. Cunningham, 421,677, February 18. *Electric Railway Motor Car*, C. J. Van Depoele, 422,266. *Electric Motor Car*, C. J. Van Depoele, 422,266. *Electric Motor Car*, I. H. Farnham, 422,339, February 25. *Supporting Frame for Electric Railway Motors*, E. Z. Priest, 422,445. *Electric Railway*, S. H. Short, 422,645. *Electromotor Engine*, S. Z. De Ferranti, 422,755, March 4. *Reversing Trolley*, H. P. Roberts, 422,976. *Overhead Electric System*, W. Vogler, 423,004. *Trolley Wire Supporting Apparatus*, same, 423,005. *Trolley for Overhead Electric Railways*, F. B. Rae, 423,391. *Electric Motor Car*, D. C. Voss, 423,400, March 11. *Electric Connection with Car Tracks*, G. G. Campbell, 423,468. *Electric Railway System*, L. Gutmann, 423,552. *Means for Supplying Electricity to Tram Cars*, A. L. Lineff, 423,874. March 18. *Electric Locomotive*, G. W. Mansfield, 424,070. *Electric Railway*, W. Thompson, 424,082. *Coupling for Trolley Wires*, S. Harris, 424,110. *Electric Railway Car*, R. M. TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

NEW THOMSON-HOUSTON ELECTRIC ROADS.

The Thomson-Houston Electric Co. has recently closed a contract with the Augusta, Hallowell & Gardiner Railway Co., of Augusta, Me., for three motor cars and an equipment of three miles of track. It is intended to operate this line between the above named cities, between which there is no means of communication now, except by the turnpike and the steam road. The construction work will be commenced as soon as the ground will permit setting poles, and it is expected to have it in operation early in the spring.

A contract has been closed by the Thomson-Houston International Co. with the Bremen Tramway Co., Bremen, Germany, for six motor cars, and two miles of electrical equipment.

The Citizens' Street Railway Co., of Indianapolis, Ind., has contracted for 6½ miles of equipment and ten motor cars.

A contract has also been closed at Pueblo, Col., with the Pueblo City railway for ten motor cars. The overhead construction will be used throughout on this line, which comprises a total of 21 miles of track.

A contract has also been closed at Port Townsend, Wash., with the Port Townsend Street Railway Co., for three cars. The line is three miles in length, and the overhead construction will be used.

The Rockford Street Railway Co. has also closed a contract for a line (overhead construction) of 6¾ miles in length and an equipment of seven motor cars.

The So. Bend & Mishawaka Street Railway Co. has closed a contract for an electric railway at So. Bend, Ind. The line will be eight miles in length (overhead construction) and six motor cars will be used.

A contract has been also closed with the Springfield City Railway Co., Springfield, Mass., for a line of two miles in length, on which six cars will be operated.

A contract has also been closed at Springfield, Ill., with the Springfield City Railway Co. for eight motor cars, and an equipment of seven miles of track, overhead system.

A contract has also been closed with the Toledo Elec. Railway Co., Toledo, O., for an additional equipment of seventeen miles of track, and twenty-five motor cars. There are already three motor cars in operation here, and 2½ miles of track have been equipped. With the additions the road will have twenty-eight motor cars, and 19½ miles of track electrically equipped.

The Winona City Street Railway Co., Winona, Minn., has also closed a contract for five motor cars, and four miles of track, and the Douglas County Street Railway Co. for the same length of track and two motor cars.

A contract has also been closed at Shreveport, La., for four motor cars, and four miles of track.

These contracts aggregate 114 motor cars, and 107.05 miles of track.

MORE ELECTRICAL MINING APPARATUS FOR THE TRANSVAAL.

We gave a description some time ago of a large installation for the electric transmission of power which was being manufactured by the Sprague Electric Railway and Motor Co. for the Forbes Reef Gold Mining Co., of the Transvaal, South Africa. This plant will transmit power from a waterfall, where are situated a number of Pelton wheels, to the mine premises, more than three miles away. The wires connecting the water wheel with the electric motors at the mine will be carried upon poles right across country in a direct line. The amount of power transmitted will be 140 h. p.

The Forbes Reef Co. are now so thoroughly satisfied that electricity is the most convenient and economical agent for transmitting power long distances, and applying it at its point of use, that the managers of that company have ordered additional apparatus, including dynamos and motors with wires for the transmission of 75 more horse power. This will make a total of 215 h. p. to be transmitted from the water power, which will be used on the mine premises. The efficiency of the whole electric system will be about 70 per cent.

When the long distance which the power is transmitted is taken into consideration this is indeed a remarkable record.

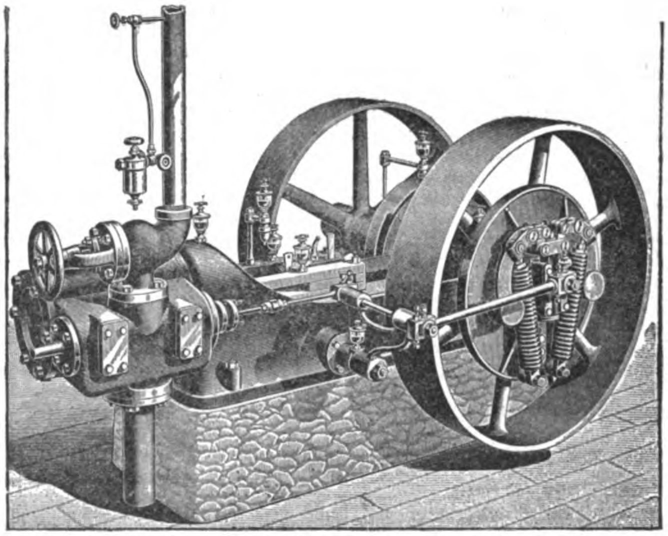
Part of this apparatus has already been shipped to the Transvaal, and the rest will follow soon. The construction and installation of this plant will be under the direction and supervision of Mr. Wm. Rydler, of the Sprague Electric Railway and Motor Co. When this is finished it will be one of the largest, if not the largest and most extensive, electric mining transmission plant in the world. While it is to be regretted that the managers of mines in this country have as yet not availed themselves to any very great extent of the advantages in the transmission of power by electricity, it will probably not be long before many of the water powers which now run to waste in a large number of mining localities will be utilized with advantage.

THE ERIE CITY AUTOMATIC CUT-OFF ENGINE FOR ELECTRIC LIGHTING.

There is probably no one factor whose influence has been greater on the design and construction of the steam-engine than the electric light, and the improvements which were inaugurated ten years ago in the high speed engine are still going on.

Among the engines which have been specially constructed for electric light service, and in which the rigorous conditions met with in that class of work are fulfilled, is that illustrated in the accompanying engraving. It is built by the Erie City Iron Works, of Erie, Pa. The engine is so constructed that the centre of the cylinder is in line with the centre of the crank shaft. The journals are well proportioned, and the bed at the crank end is wide, thus securing a broad surface bearing upon the foundation. The steam ports are short, and afford ready exit for the exhaust; they are covered by removable plates, thus allowing easy access for inspection.

The piston valve is perfectly balanced, and the valve stem is supported at the front end by the stuffing box, and at the back end by the back steam chest head, which has an outward extension for this purpose. This relieves the valve seat of the weight of the valve, and reduces the wear to a minimum amount. The crank shaft is cut from a solid forging, the counter balances are large in diameter, and all the bearings are well finished. The best form of connecting rod has been adopted and the boxes are strong and well babbitted; the crosshead is extra heavy, and the wings are spot babbitted. The bottom slides are independent of the bed and can be adjusted for wear. The piston is wide and packed with sprung rings, fitted and turned to give the best results. The valve stem is of steel, and the valve is properly adjusted when the engine is tested at the works. The governor is independent of the driving pulley, which is an important feature; it is simple in construction and has but few parts.



The Erie City Engine.

It will also be noted that the rocker arm operating the valve is connected to the governor outside of the fly-wheel. By this arrangement the eccentric is done away with and the fly-wheel is brought close to the main bearing, so that the constant tendency of the main shaft to bend and bind in the bearings with consequent heating is avoided.

The engine is substantially built throughout with interchangeable parts finished to templets, and it varies in size from 30 h. p., running at 300 revolutions per minute, to 125 h. p., running at 250 revolutions.

The Eastern Electric Light and Storage Battery Co. are meeting with so much success with the Sorley battery, that they are now looking around for suitable premises for the manufacture of these batteries. They are at present supplied by the Anglo-American Storage Battery Co., of New York.

EUREKA TEMPERED COPPER FOR ELECTRICAL WORK.

Copper enters so largely into the construction of electrical apparatus, especially under conditions where it is subject to wear that any means by which its life can be increased must prove of value. This is specially the case with commutator strips, brushes, switch contacts and the like, the renewal of which is a constant source of expense. In order to avoid this the Eureka Tempered Copper Co., of North East, Pa., have recently brought out a quality of copper which is tempered or toughened by a secret process, and by which its life is greatly increased without affecting in any way its conductivity.

This quality of copper is also well adapted for bearings and journal boxes for electric motors and dynamos, trolley wheels, cut-outs, etc., and in general for all surfaces subject to friction.

THE NEW YORK INSULATED WIRE CO.

The above concern, of 649–651 Broadway, are enjoying a large measure of prosperity, and have yet to find the limit of the field in which they are working so actively. Mr. J. Godfrey, has been in New Orleans lately, and has filed some large orders from that district. In Detroit he has established a new agency in the hands of the Fisher Electric Co., of that city, and the first order from that quarter mounted up into hundreds of thousands of feet.

The company have lately been engaged making up a carload of wires, cables, etc., for their Chicago agents, the Knapp Electrical Works, 54–56 Franklin street, that city.

Mr. George H. Meeker has been selected by Mr. Gallaher as Mr. Godfrey's assistant, so that the territory which has grown altogether beyond the ability of any one man to cover may be property looked after. Mr. Meeker will work along the lines so successfully laid down by his chief, and there is no doubt that his work will add to the company's reputation and revenues.

A recent order received by the company was for a Brush plant at Yokohama, Japan.

THE INTERIOR CONDUIT AND INSULATION CO.

A certificate of incorporation of the Interior Conduit and Insulation Co. was filed in the county clerk's office a few days ago. The objects of the company are to manufacture tubes for electrical wires. The capital is placed at $1,000,000. The trustees are E. H. Johnson, Sigmund Bergmann, John H. McClement, Edward T. Greenfield and Philip Klein. All these gentlemen are well known in connection with prosperous and progressive electrical enterprises, and the interior conduit has already in a most remarkably short space of time, made a splendid record in popularity and efficiency as a means of carrying wires of all classes into and throughout buildings of every class. The company is the successor of the Interior Electrical Conduit Co., which in a few months outran its extensive manufacturing facilities, and which now with larger capital and increased forces is going in for the work that awaits it. The new company will also do a large business in the supply of its special form of conduits for out-door, underground work, such, for example, as that in connection with the disposal of supply wires to electric railway lines, and the general work of electric distribution over a large area from central lighting and power stations.

THE CONTRACT OF THE STANDARD SUBWAY COMPANY HELD DEFECTIVE.

The General Term of the New York Supreme Court has reversed Judge Andrews's decision, and has renewed the injunction which prevents the Board of Electrical control from awarding the proposed subway contract to the Standard Subway Company. There were two suits, one by the Manhattan Electric Light Company and one by Taxpayer Armstrong. So far as the corporation's suit is concerned the General Term sustains Judge Andrews, but it holds that the taxpayer is entitled to an injunction. Armstrong's suit was brought to buttress the other.

The Court says that Armstrong had a right to sue, and that the main question is whether the contract he seeks to prevent is an illegal official act. The company holding the present contract says it cannot complete the work now ordered in less than two years. The Court continues:

"It has not refused to proceed with the work, but in consequence of an arrangement or understanding entered into with the Standard Electrical Subway Co. it proposes to surrender and assign all its rights and interests in certain portions of these contracts and the work it has already performed to the latter company, and to carry this arrangement or understanding into effect a contract has been proposed by the Standard and sanctioned by the city of New York, and whether this contract in this manner accepted is one which the acts already mentioned will allow to be executed and carried into effect is the more important part of the controversy now before the Court."

The opinion goes on to say that it was the purpose of the Board of Electrical Control, as expressed in its resolution of February 19, 1890, that the subways therein designated should be built within the year 1890. But the Court continues:

"This resolution has been made no part of the contract which it is proposed shall be entered into. Neither has the party with whom it is proposed to make the contract been in any manner obligated by its terms or its necessary implications either to construct the subways within the current year or in the streets and avenues mentioned in the resolution."

The proposed contract with the Standard company is defective. It does not provide that the company shall build such subways as the Board may direct it to build. It does not embrace the streets mentioned in the resolution of the Board of Electrical Control. The contract does not provide within what time the subways shall be built. The Board has gone beyond the power given it by statute in some of the provisions. While the city is empowered to purchase the subways after January 1, 1897, subject, nevertheless, to leases and mortgages, no provision is made to limit the amount of encumbrances the Standard company may put on the subways. The statute fixed the mortgage limit at 50 per cent. The Court says:

"The company, by the terms of the contract, would be enabled, by the placing of excessive mortgages upon the property, to prevent the city from becoming a purchaser.

"The proposed contract would leave it to the volition of the Standard company to construct subways or not, as it might afterward determine to be most expedient for its own interests.

"The plaintiff is in a position as taxpayer to prevent this illegal contract from being subscribed and completed, certainly until it shall be made entirely definite and clear that the rights of the public will be subserved and effectively secured."

THE BERGMANN ELECTRIC AND GAS FIXTURE COMPANY.

The above company, in their extensive factory at 527-537 West Thirty-fourth street, near the North River, have already built up a prosperous and progressive business, which keeps each of the seven stories humming like a hive. Not only is the fixture industry here developed to its fullest extent, but special attention is given to the construction of new forms of apparatus, either in single experimental sets or in large quantities; and altogether some 400 men are employed in the various departments. The fixture work is divided up into the foundry, iron work, dipping and depositing, chasing, modeling, brass spinning, glass working, buffing, lacquering, plating, assembling, shipping and other departments, in many of which old processes have been skillfully improved or new ones have been brought to perfection. Some fine work can be seen in hand at any time in the wrought-iron, brass spinning and chasing departments, and Mr. Bergmann has one or two artistic productions coming along that are likely to arouse very general interest and admiration. Some idea of the care bestowed on the details of glass work may be formed from the fact that when the writer squeezed his way through the crowded factory he found in that department one of the skilled heads of it putting together 300 pieces of special stained glass in a beautiful shade or globe for a leading railway magnate's house. On the electrical instrument floor, it may be mentioned, model apparatus is in hand all the time, and among the company's recent efforts for inventors have been new telegraphic apparatus, a new meter, and new arc lamps, of which they are now making a great number for direct commercial introduction. This is surely range enough. Mr. G. A. Scott, the electrician, is gradually getting together a neat testing outfit in his laboratory, so that he will have no difficulty in making the most delicate measurements as occasion arises.

The company have, of course, electric lights all through the factory, and run one of the big old Edison dynamos by a Watts-Campbell engine. It is worthy of note that the dynamo, which is one of Mr. Bergmann's pets, is doing as good work to-day as it ever did, with a commutator as smooth as glass or a maiden's cheek. The engine power is to be greatly increased to meet the growing demands of the factory.

In the front of the building the offices are located, on the ground floor. A full line of the company's handsome productions is carried at the show rooms, Fifth avenue, this city. At one or other place may be found in business hours, and hours when most business men have gone home to rest, Mr. Sigmund Bergmann, the president of the company, and a pioneer in electrical work; Mr. E. F. Caldwell, vice-president, well known for his skill and taste in design; and Mr. P. H. Klein, the secretary and treasurer, on whom devolves a large part of the conduct of the large business.

THE USE OF LIGHTNING RODS FOR STATIONS.

MR. J. D. WEST, of 40 Cortlandt street, who has long made a specialty of the lightning rod business, writes us a pertinent letter, as follows:

"In view of the frequent invasions of electrical stations by intensified electrical disturbances, would it not be a safeguard if the buildings containing such stations were properly covered on their outer angles with lightning rods of such construction as will freely receive and disperse throughout their entire circuit, and thus equalize the tension all about the building. The Mount Morris plant has such rods; would it not be well if others were thus protected?"

THE CROCKER-WHEELER ELECTRIC MOTOR CO.

The above company are in receipt of advices from their London agents, stating that they have secured the first prize for the Crocker-Wheeler motor at the Birmingham (England) International Exposition. The motors have been shown by comparative tests to have decided advantages in efficiency, durability, simplicity and design. Accompanying this gratifying information is an order for 14 motors, including fan outfits and electric pumps. Both facts are additional proof of the ready appreciation now being shown in England of American electrical apparatus of good workmanship and based on sound engineering principles.

The company have recently appointed Mr. T. McCoubray to the position of secretary and general agent, with offices for the present at the head-quarters, 322 and 324 7th avenue. Mr. McCoubray is well known as having held for a time the secretaryship of the National Electric Light Association. He was also connected later with the old Baxter motor company and was entrusted with the management of its New York office. He brings to his new duties a wide acquaintance and a ripe experience with motor work, as well on the engineering as on the commercial side.

THE "HELMET BRAND" WIRE.

The increasing demand for a good insulated wire at a lower price has led the Empire City Electric Co., of 15 Dey street, this city, to place upon the market a new wire under the trade-mark of the "Helmet Brand."

If the reputation of the company is at all a guarantee of the quality of the wire, it cannot fail to meet the requirements of consumers. It is being manufactured by the company in large quantities and is meeting with a ready sale.

With regard to the new products of the company, it is worth while quoting their own language. "Of the "O. E." weatherproof wire they say: "This wire is especially adapted for all kinds of line work and also for inside wiring where it is not necessary to use the highest grade of insulation. It has a hard smooth finish, does not soften or crack under extremes of temperature, is water-proof and able to withstand a great amount of abrasion. For tree-work and unusually damp places the insulative efficiency may be increased by additional braids. The covering consists of an insulation, a saturated braid, and a water-proof finish which also adds to the insulative qualities of the wire."

Respecting the "E. T." taped and braided wire they say: "This wire is essentially for line work, has a very high insulation and will withstand the action of the weather without deterioration. Being thoroughly water-proof and not affected by acids or gases, it is of especial service wherever a high grade of insulation is needed. The materials used in making this insulation are such that of necessity the wire is especially adapted to withstand abrasion and rough usage. The covering consists of an insulation, a saturated braid, two uncured rubber tapes wound in opposite directions, an insulation, a braid and a weather-proof finish. This is one of the best insulated wires ever offered to the trade."

Not satisfied with these new departures, the company promise to have other special grades ready at an early date.

THE TROPICAL AMERICAN TELEPHONE COMPANY.

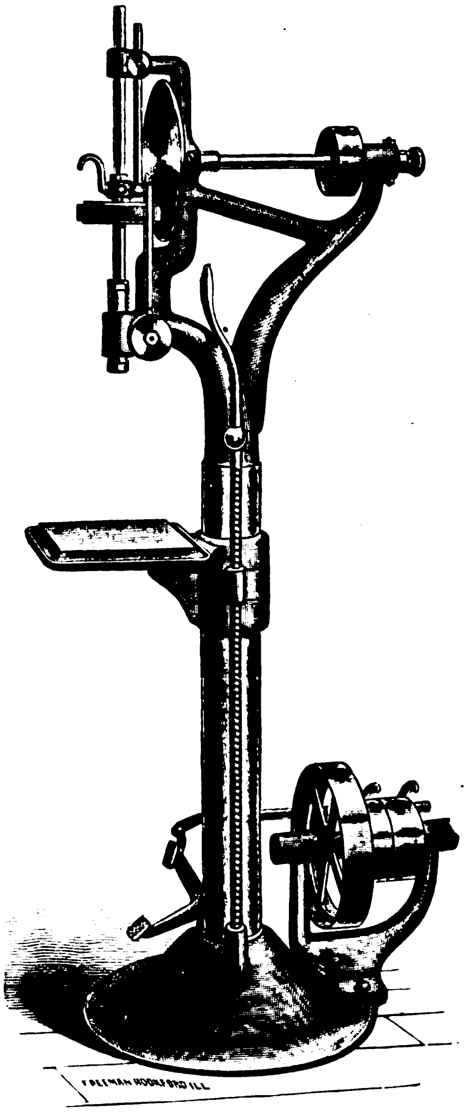
The export business to South America, Central America, and the West Indies in telephones, magnetos and telephonic apparatus of the Tropical American Telephone Co., of Boston, has increased so rapidly that it has necessitated the employment of a large corps of experienced men in the New York office and the establishment of branches in other cities. Mr. Frank W. Harrington, so long and favorably known as salesman for the Western Electric Co., of New York, has been induced to take charge of the Tropical American company's New York branch, and assumes his duties on April 1, to assist Mr. H. W. Bates, who has been in charge there since June 1889. Mr. Harrington's large experience in the telephone field will make his services very valuable. He was formerly with Mr. Charles Williams, Jr., when his large establishment at 109 Court street, Boston was known as the headquarters for the manufacture of telephones, transmitters, magneto call bells, switch boards, and telephonic apparatus and supplies, the Bell system of electrical devices having been built under his eye, and largely through his energy and inventive genius. Mr. Williams, who is said to be the largest individual stockholder in the Western Electric Co., is now President of the Tropical American Telephone Co., succeeding Colonel Henry S. Russell, who retired from active business some time ago. Mr. Harrington will now be located at 18 Cortlandt street, and exporters and commission merchants will find him ready at all times to furnish quotations for every kind of telephonic apparatus. The Tropical American company will soon issue a neat pamphlet setting out in full its telephonic rights in its territory.

CLARK ARC LAMP FOR CONTINUOUS INCANDESCENT CURRENT.

The Clark Electric Co., 192 Broadway, New York, have, it is claimed, the safest and most efficient arc lighting system in this country. The many new features invented by Mr. Clark, the electrician of the company, are exceedingly valuable. Among the latest are the Clark automatic safety device for high tension currents, for shunt-wound dynamos and alternating dynamos, and the Clark arc lamp for continuous incandescent currents. This lamp is being used for interior lighting in New York. The Columbia College authorities of this city have used it for over a year with perfect satisfaction. The illuminating power of the lamp is, it is asserted, the greatest of any arc lamp made. It is perfectly steady, and does not hiss or flicker, and is entirely noiseless. This supplies a long felt want where it has been found objectionable to operate arc lights indoors. It is well known that colors show the same by arc light as by daylight, and that the arc light is the cheapest illumination in the world, considering the cost of its production; hence, with the other essentials added, it proves irresistible.

THE NEW BARNES SENSITIVE DRILL.

THE sharp competition existing between manufacturers in all lines of electrical work makes it necessary for them to employ only the most perfect tools and machinery in order to produce their goods to the best possible advantage. This demand for improved machinery has stimulated the inventive faculties of our mechanics and engineers, with the result that new machines are being produced, which, considered in relation to their special adaptation for the purposes for which they were designed, are almost absolutely perfect.



The New "Barnes" Sensitive Drill.

As a case in point, attention is called to the new sensitive drill made by the W. F. & John Barnes Co., of Rockford, Ill. The drill is illustrated in the accompanying engraving, and it will at once be seen that the principles involved in its construction mark a departure from other tools of this kind.

The drill is adapted for use in the manufacture of electrical appliances, builders' and cabinet hardware, and, in general where the drilling is not large, but where delicate adjustment and rapid and effective operation are essential.

It is in the strictest sense of the word a *sensitive* drill, for the variations of speed and power are so completely under the control of the operator and the adjustments so perfect, that the person using the drill is always able to determine the pressure which is being applied. Herein lies the economy of this new tool in the preventing of the breakage of twist drills.

All the adjustments of power and speed can be made instantly without shifting belts or stopping the machine.

CONTROLLING DISTANT WATER GATES BY ELECTRIC MOTOR.

The displacement of steam-engines and other engines by the electric motor for general work has become so common an occurrence that it is now looked upon as a matter of course, and it is only the application of electric power to work which could not be done by any other means that elicits more than ordinary attention. A case in point is the movement and control of hydraulic gates at a distance of several miles from the point of operation. The Elektron Manufacturing Co. of Brooklyn have recently built two Perret motors for this purpose, one to be used at Marion, O., at a distance of three miles, and the other to be used at Decatur, Ala., at a distance of a mile or more from the operator. The dynamo used in each case is a small constant current machine. By changing the direction of the current at the dynamos, the motors, which are series wound, are run in either direction at will.

It is of course well known that with an ordinary series motor a change in the direction of the current on the line does not change the direction of rotation of the armature, because the current in both field and armature is reversed at the same time. In the case in point the reversal is effected by an ingenious automatic device invented by Mr. Frank A. Perret, the electrician of the Elektron Manufacturing Co.; this is attached to the motor and keeps the polarity of the fields unchanged regardless of change in direction of the current on the line, while the current in the armature, and consequently its direction of rotation, is reversed with each change in the main current. The water gates are thus controlled and placed in any desired position at the will of the operator, miles away, by simply turning a switch lever.

TALK OF "TRUSTS" AND COMBINATIONS.

The air has been, and continues, as thick as a sea fog with talk of trusts and combinations and new moves on the part of the larger electric light companies. One paragraph last week credited Mr. Henry Villard with a plan to form a big banking corporation to attend to the work of the Edison and allied interests. Another paragraph, which has done duty all over the country, is as follows:

"BOSTON, March 24.—Negotiations are in progress for the forming of an electric light and railway trust. The three great electric companies of the country are the Westinghouse, the Edison, and the Thomson-Houston. These companies control all the important patents for electric lights, both arc and incandescent, and for electric motors for street railways. The Thomson-Houston management proposed to the Edison people some time ago that the motor business of both companies be transferred to a new company, the profits of the new concern to be divided proportionately between the two. Later it was proposed that not only the motor interest, but the whole business of the two concerns be transferred to a trust. For this purpose, so it was stated to-day, all the large holders of Thomson-Houston stock have been asked to deposit their shares with five trustees, ex-Governor Ames and Messrs. Pevear, Duncan, Newhall and Sanford. Further, it is asserted that within two weeks overtures were made to George Westinghouse to have his company come in. His reply is not known, but "the street" has it that his acceptance is not unlikely. An electric light and railway trust could easily pay 10 per cent. on a capital of $50,000,000."

It is needless to say that some of this talk is mere wind, and that the rest of it is met with confirmatory denial or negative admission by those least interested.

SCHIEREN BELTING FOR ELECTRIC LIGHT PLANTS.—The house of Chas. A. Schieren & Co., 45–51 Ferry street, this city, have just secured a contract from the Louisiana Electric Light Co. of New Orleans, La., for 160 feet of 72-inch oak tanned double belt and 550 feet of 48-inch. It is stated that the 72-inch will be the largest belt ever furnished to an electric light plant, and will be the largest and heaviest belt in the world. It will be put together in the firm's new "Baby" hydraulic belt press. This "Baby" weighs 12 tons, is capable of making a belt 74 inches wide, and has a capacity of over 300 tons pressure. This order is a remarkable instance of the manner in which modern electric lighting makes a draft upon all the engineering and industrial resources of mechanics.

NEW UNITED STATES INCANDESCENT PLANTS.

MR. E. G. BERNARD, the well-known special agent of the United States, Sawyer-Man and Westinghouse Electric companies, reports a number of recent contracts and installations that he has made, including A. B. Morris, Amsterdam, N. Y., knit goods, 150 lights; Dun, Smith & Co., Fort Plain, N. Y., knit goods, 100 lights; Little Falls, N. Y. Paper Company, 50 lights; Standard Furniture Company, Herkimer, N. Y., 300 lights; Felts Falls Paper Company, Watertown, N. Y., 200 lights.

Mr. Bernard is, naturally, a little proud of his success among the knitting mills.

THE EDISON MACHINE WORKS.

The great Edison factories at Schenectady are reported to be busier than ever before, and vast extensions are to be made during the current year. When the plans have been fully carried out, the works will be twice their present size, and that point will probably be reached this summer. The force of men employed will also be greatly increased, and the total number will be 2,500 to 3,000. Activity prevails in every department, and much difficulty is experienced in keeping pace with orders. Mr. S. Insull, the manager, whose health broke down under the strain a few months ago, has just returned from England, whither he went for change and rest, thoroughly restored. During his stay abroad he took occasion to make close observation of work being done in London and on the Continent.

THE NEW FACTORY OF THE ANGLO-AMERICAN ELECTRIC LIGHT MANUFACTURING COMPANY.

The above-named company secured recently at a low price a very advantageous factory at Kensington, Conn. Mr. C. Sorley, its electrician and the inventor of its storage battery, has since been busily engaged laying out the premises in accordance with the new work and requirements. The old foundry building has been split up into five rooms, one 40x40 for powder preparation; one 118x40 for plate making, &c.; one 116x40 for charging; one 100x40 for the dynamos, with solid brick and cement foundations; one for boiler, etc. The factory also has a large water power plant of 200 h. p. New offices and warehouses have also been laid out.

The company has been giving out large orders for supplies, &c., and has contracted for eight Edison dynamos of 30 volts and 50 amperes each. The new factory will soon be in shape to do work on a very extensive scale. Mr. Bernard Lande, the general manager, has his headquarters at the company's office in the Times Building, this city.

TRADE NOTES.

THE WAINWRIGHT MANUFACTURING COMPANY, of Boston, have received an order from the Detroit Electric Light Company for a 300 h. p. heater.

OKONITE.—The new factory of the Okonite company located at Dundee, N. J., is completed, and the makers of Okonite wires and cables are exceedingly busy filling orders for these popular goods. There is a brisk demand for the Candee aerial wire also.

BERGMANN & CO., of East 17th street and Avenue B, are extremely busy in all their departments, and are filling some heavy fixtures and supply contracts. They have recently made some new departures in artistic electro-metal work, and the results are very creditable to their enterprise and taste.

THE NEW YORK BELTING AND PACKING CO., with headquarters at 15 Park Row, this city, manufacturers of vulcanized rubber goods for mechanical purposes, find a steady call for their well-known wares. They make a superior quality of belting for use on dynamos and other swift running machinery, which is attracting attention in electrical circles.

THE GOULD & WATSON COMPANY, of Boston, continue to receive large orders for moulded mica insulators for line construction work for all systems from all over the country. They are now making a specialty of a non-combustible insulation for switches, cut-outs, rosettes, etc., which have received the endorsement of the Boston Fire Underwriters' Union. Several important orders have recently been received from England for small insulating pieces for street and trolley line work, chiefly to be used in European countries.

THE WESTON ELECTRICAL INSTRUMENT CO., of Newark, N. J., are full of business. The Weston standard voltmeters and ammeters made by them have now been in use for over a year and in every case have givn entire satisfaction. Dr. Edward Tatum, of Philadelphia, in writing to the manufacturers, under date of August 17, 1889, says: " * * * I regard your voltmeter quite without a rival, as a combination in one instrument of the following qualities: extent of range with the great convenience of strict proportionality; complete absence of friction; quite new of action; accuracy throughout the scale."

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed*, EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. IX. NEW YORK, APRIL 9, 1890. No. 101

The advance of science is not in simple proportion to the time; the next fifty years will probably see a far greater advance than the one hundred years since the date of Franklin's electrical work has seen.—Professor John Trowbridge.

EXTENSIVE ELECTRIC RAILWAY WORK.

WHEN the winter now ending set in it was hardly expected that the mildness of the season would permit a very great activity in electric street railway work. But it may be doubted whether at any one time the companies putting in roads were able to catch up with the contracts, and now, as spring opens, it finds them not only with heavy orders in hand, but with a promise of new work that must far transcend the most sanguine forecasts of everyone concerned. While there are a large number of new roads to be built, of moderate size, attention and interest naturally centre in some of the leading cities. St. Louis, for example, will have at least eight or nine electric roads building this spring, the city authorities having been liberal in their concession of franchises. The work in St. Paul and Minneapolis is alone enough to occupy the energies of nearly all the men in the country familiar with the details, as engineers or laborers. In Rochester a contract has just been closed for 50 miles of track and 100 cars. In Pittsburgh several of the roads intend to adopt electric traction, and the Duquesne company has already contracted for 100 Pullman cars. Among other cities that may be mentioned as adopting the new mode of urban travel are Memphis, Atlanta and Chattanooga.

Evidently the construction of these roads will call for the expenditure of many million dollars, with a corresponding stimulus to electrical manufacturing and supply industries. It is to be feared that in some instances the rush and pressure will lead to bad work. This is specially to be deprecated and avoided. We know of no class of construction in which cheapness and poorness of skill and material lead more quickly to disastrous results than the electrical, just as there is none in which honest workmanship makes itself more quickly apparent.

THE PARIS METER COMPETITION.

WHEN, about one year ago, the city of Paris announced its intention of awarding a prize of 10,000 francs to the meter best adapted to its wants, it was supposed that the competition thus brought about would result in a definite selection. It was pointed out at the time, however, that the clause in the conditions of the contest giving the city of Paris the right to use the successful meter without further payment of royalty would prevent the entrance of many inventors, and this has, to some extent, been the case, as admitted by the commission appointed to adjudge the award. Nevertheless, all the more prominent meters employed in Europe, together with a few of American origin, were entered, with the result detailed more fully elsewhere. None was found to fulfill entirely the required conditions. Considering the great strides that have been made in all electrical branches during the last 10 years, it cannot but be considered a matter of surprise that thus far no device has been forthcoming which is able to satisfy the Paris Municipal Commission. Recognizing the undoubted value of some of the meters submitted, however, the commission have awarded various sums of money as an *encouragement* to their inventors. Taking into consideration the short time given to inventors to prepare for the test, as well as the restrictive clause relative to forfeiture of royalty to the city of Paris, the municipality has decided to open another competition from which these features are eliminated. We hope that American inventors will be more numerously represented in this second competition than they were at the last, and that they will more nearly conform to the conditions laid down by the commission. The faith of the commission in the ability of electrical inventors to provide an adequate meter is highly flattering.

Electric Railway Traction.

EARLY in the practice of electric traction, the phenomenon was observed, and probably first by Mr. Leo Daft, that the tractive power of the electric car was increased by the action of the current passing between wheel and rail. The exact nature of the phenomenon, which has been ascribed more particularly to a temporary welding action, has not yet been arrived at, nor have any systematic experiments to determine the extent of the action been published hitherto. Our readers will, therefore, be interested in the article by Mr. O. T. Crosby, in which he gives the results of a series of tests to determine the influence of this phenomenon on street-car traction. The conclusions arrived at by Mr. Crosby are negative, and would go to deny the assertion that any action takes place. Mr. Crosby admits that his experiments lacked somewhat in delicacy, but cites in support of the results obtained by him the fact that electric railways with overhead metallic return, and hence without current between wheel and rail, are able to mount quite as heavy grades as those in which the earth and rail are so employed. It will be noted, however, that all of these experiments were made with the car stationary, so that there was no means of ascertaining the effect of the supposed action with the wheels in normal rolling motion. While, in the absence of data, it might be difficult to predicate a difference in the results obtained, it would certainly be of value to determine this point under the conditions indicated; and we hope Mr. Crosby will continue his investigation in this direction. Incidentally, also, Mr. Crosby draws attention to a fact of some importance, which involves the question of economy as well as safety in operation, and that is that frequently far more current is applied to the motor at starting than is required for the purpose. The remedy for this is obvious.

Alternating Current Phenomena.

THOSE who had the pleasure of listening to Professor Thomson's admirable Institute lecture, of which we give an abstract elsewhere, could not but have been convinced that the alternating current opens up a vast field of new electrical applications. By the aid of our simple illustrations, sketched during the lecture, the reader will be able to gain at least a fair conception of the beauty and variety of Professor Thomson's experiments, carried out with that ease and in the convincing manner for which the distinguished author is so justly celebrated. One cannot suppress the thought that notwithstanding the extent of the phenomena and of their application thus revealed by Professor Thomson, he and others may be expected to develop many more of no less interest and practical value at no distant future.

Secondary, Primary and Storage Batteries.

WHILE the electrical units, based on physical constants, are now thoroughly defined and can give rise to no ambiguity, there are still a number of terms used in the science and art of electricity that require closer definition and restriction. This was perhaps most forcibly illustrated in the recent storage battery litigation, where much ingenuity was applied, and we had almost said wasted, in attempting to define the similarity, or difference, between the primary and the secondary battery. Leaving out the question of the appropriateness of the term "storage battery," which is objected to by some as unscientific, Mr. E. R. Knowles, in discussing the terms, finds each of them to be capable of distinct definition, and seems to make a fitting place for the term "storage battery or accumulator" in electrical nomenclature.

Municipal Control of Lighting Plants.

SOME interesting figures appear in this issue from Mr. Victor Rosewater, of Johns Hopkins, intended to show that it is cheaper for municipalities to make their own electric light than for them to buy it; and hence, that it is proper for them to instal and operate their own plants. Mr. Rosewater has been at some trouble to collate his figures, but they are neither complete nor conclusive. They should include, for instance, a distinction between steam power and water power plants, or the relative distances from coal supply, and the different costs of fuel. The argument for municipal control made is also weakened by the absence of any allowance on the score of taxation. A local company would bear its share of taxation in more ways than one, but a municipal plant simply shifts an extra burden to the taxpayer who is already charged with heavier taxation in order to meet the interest on the bonds, or on the other indebtedness of the community incurred in order to put the plant in. Then it is an altogether wrong assumption that lights should be cheaper in a city than in a small place, because more of them are rented from a company. A city plant pays higher rent, higher salaries, higher taxes, and is at vastly more expense than a rural plant in running its circuits, whether overhead or underground. There are other points that arise, but enough has been said to show that Mr. Rosewater's figures will stand revision as a basis for argument, or as a reason for the diversion of taxation.

The Electrical Demand for Copper.

ONE of the principal items entering into the manufacture of electrical apparatus and goods is copper. Perhaps a better appreciatian than generally obtains of this fact may be formed from the statement which we heard last week, and is true, that one of the large companies had just placed an order for 1,000,000 pounds of copper, and had at that time an order in for 250,000 pounds more. Enormous as this quantity may seem, it is understood that it will all be used up by July 1. The activity prevailing may readily be inferred from these figures, which are those of a single concern, though, of course, it is one of the most prominent.

Tests of Incandescent Lamps.

IN our last issue we brought to a close the articles by Mr. Puffer on the efficiency tests of various incandescent lamps, in which the author pointed out again in a forcible manner the discrepancy which exists in the illuminating power of the "16-candle power" lamps of various manufacturers. Though worthy of remark and, we hope, open to remedy, the difference here observed is not nearly so great as might be found in comparing the illuminating power of what is sold as "20-candle gas." Mr. Puffer quite correctly lays stress upon the fact that the value of an incandescent lamp ought not to be judged from the results of a few hours' burning, and it is therefore all the more to be hoped that his work will soon be sufficiently advanced to include a "life test" with continuous measurements of illuminating power at consecutive intervals. The results of such a test, combined with Mr. Puffer's method of combined efficiencies, would afford an interesting comparison with the Franklin Institute tests of 1884.

Greatness in Small Things.

THE field of application for the small electric motor is so vast that the construction of these machines was begun some time before the larger motors were thought to be sufficiently far advanced to warrant their practical application. But in the haste to perfect the larger, the smaller prototype lost ground, comparatively, again, and has until recently been very much neglected. Now, however, that the proper attention is being given to the subject, results are obtained which place these pigmies almost, if not quite, on a level with their more powerful brothers in point of economy. The means by which this gradual evolution has been accomplished are well described in this issue by Mr. F. B. Crocker, who shows that by studying and analyzing each element of construction and source of loss a result may be arrived at which places these machines easily in the front rank of prime movers.

ARTICLES.

CARE IN MOTOR TESTING.

BY FRANCIS B. CROCKER.

The development of the electric motor has been so very rapid that there has been but little generosity shown in giving care and time to its construction. From the moment of the first conception of a motor till it is finally put into use, every step in its production has been characterized by a haste that it would be difficult to find anywhere equaled, except perhaps in a fire engine station just after an alarm has been sounded.

The testing of electric motors has suffered more from this haste than any other department of the work, the idea being that it is only necessary to build a motor in order to sell it, while the testing can be replaced by hope that the motor may work properly.

We have passed, however, the period of this excessive haste and we should now give the most careful attention to each detail of electric motor design, construction and testing.

In connection with motor testing, Dr. S. S. Wheeler and the writer have recently gotten up several methods to facilitate and perfect this work.

We have had tables prepared giving the electrical horsepower for each volt and ampere from zero to the ordinary limits of practice; horse-power at the different speeds and torques; and current required to run motors of different power at various efficiencies. By these tables we can translate our results instantly without interrupting our work. If it is necessary to stop and go through a long calculation, the results lose their force. These tables must be complete and give each unit and fractions if possible; a table which skips by fives or tens is practically useless. We use also a test sheet which is much more complete than those generally used, giving over one hundred of the principal facts about a motor, and we find that we are able to detect and trace the cause of the smallest differences between motors by comparing their test sheets.

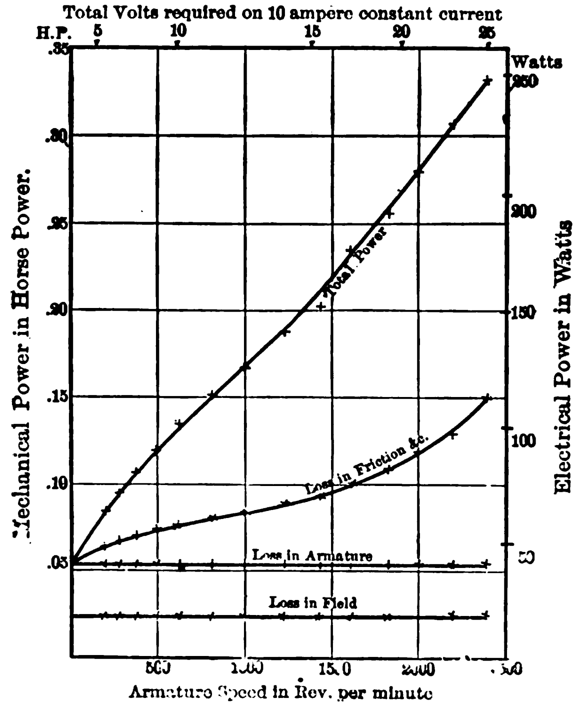

FIG. 1.

Another very useful aid employed by us in our work consists of a sheet ruled into squares, as commonly used for tracing curves, but made of convenient and uniform size with blank columns for observations on the side.

The use of this "curve sheet" is illustrated in the two accompanying diagrams. The first, Fig. 1, shows the results of a test on a small (1-8 h. p.) motor series wound for a 10 ampere constant current arc circuit. The abscissæ or horizontal distances represent the armature speed in revolutions per minute, and the ordinates, or vertical distances on the left, represent power in horse-power. At the top the volts corresponding to different speeds, and at the right hand side the electrical power in watts, are also given for comparison. The vertical distances between the axis and the lower horizontal line marked "loss in field" represent the electrical energy ($C^2 R$) consumed in the field, which is constant because the current and resistance are both constant. The distances between this line and the next line, marked "loss in armature," represent the energy lost in the armature resistance, which is also constant for similar reasons.

The upper inclined line represents the total electrical power supplied to motors at different speeds. This is equal at zero speed simply to the loss due to armature and field resistance, about .05 h. p., and increases almost uniformly to .335 h. p. at 2,400 revolutions per minute. The power actually developed by the motor at different speeds, as measured by Prony brake, is then laid off downward from the upper line, giving us another inclined line; the vertical distances between these two lines, therefore, show the net power produced at any given speed. The total vertical distances between the lower inclined line and the axis show the total losses in the motor, and the two horizontal lines show the losses due to armature and field resistances. Thus the vertical distances between the upper horizontal line and the lower inclined line represent all other losses, which are principally friction and Foucault currents. The rapid rise of these latter losses at high speeds is the most noticeable feature of the diagram.

The diagram, Fig. 2, illustrates a similar diagram made from tests of a 1-6 h. p. shunt wound motor on a constant potential circuit (110 volts). The striking analogies as well as differences between the two cases are quite interesting.

The present diagram, like the previous one, is plotted primarily with respect to power and speed, the vertical distances representing power in horse-power and the horizontal distances representing speed in revolutions per minute. At the right hand side the power is also given in watts, and at the top the total current consumed is given in amperes. In this way the relation between the various quantities is very clearly shown.

The vertical distances between the different curves represent the energy consumed in each case. For example, the energy consumed in the armature at 2,000 revolutions is measured by the vertical distance between curves A and B on the line through 2,000 revolutions.

The shunt machine in this diagram of course shows a constant consumption of energy in the field, which was also the case with the series machine, since both machines have a constant field resistance and are fed with either constant current or constant potential; therefore the loss due to resistance ($C^2 R$) is constant. The shunt machine shows, however, a variable loss in the armature, which is not the case with the series machine. This variable loss in the armature is due to variations in current caused by changes in speed and, therefore, changes in counter E. M. F. This loss in the armature increases more and more rapidly with increase of current, since it varies as the square of the latter. This armature loss is, of course, greater at the lower speeds because the counter E. M. F. is then less and the current correspondingly greater. The extremely small loss in the armature at the high speeds is remarkable; even at 2,000 revolutions, when the motor is actually developing 1-8 h. p., the energy lost in the armature is only 10 watts, about 6 per cent. of the total energy consumed, which is very low in such a small machine.

When the motor is loaded to its full capacity at 1,800 revolutions, and is then developing 1-6 h. p., the loss in the armature due to resistance is 20 watts. This increased loss is much greater than the increase of power developed because, as already stated, the former varies as the square, and the latter only as the first power, of the current.

The armature resistance loss at full load, 20 watts, is almost equal to the loss in the field, which is 27 watts. The general rule is that the two should be about equal at full load, but it is preferable to have the armature less as it runs at more constant speed if it is of low resistance.

The vertical distances between the two curves B and C represent the sum of the losses in the motor due to friction, Foucault currents and resistance of air. It will be noticed that these losses are practically constant from 1,800 to 2,000 revolutions, having a value of about 22 watts or .03 h. p. Above 2,000 revolutions the loss increases quite rapidly and becomes almost 50 watts at 2,250 revolutions, the speed at which the motor runs free. This increase in these losses at high speeds might be expected, and is shown in the diagram to be very marked.

It will be noticed that the three kinds of loss, *i. e.*, field resistance, armature resistance, and that due to friction and Foucault currents, are almost exactly equal to one another at 1,800 revolutions when the motor gives its full power. This uniform distribution of loss is very satisfactory because it tends to produce uniform action of the machine, and it indicates, moreover, that there is no one cause of loss which is excessive. It is very obvious that if any one part of the machine, the armature coils, for instance, produced any abnormal loss, they would be heated to a very objectionable degree.

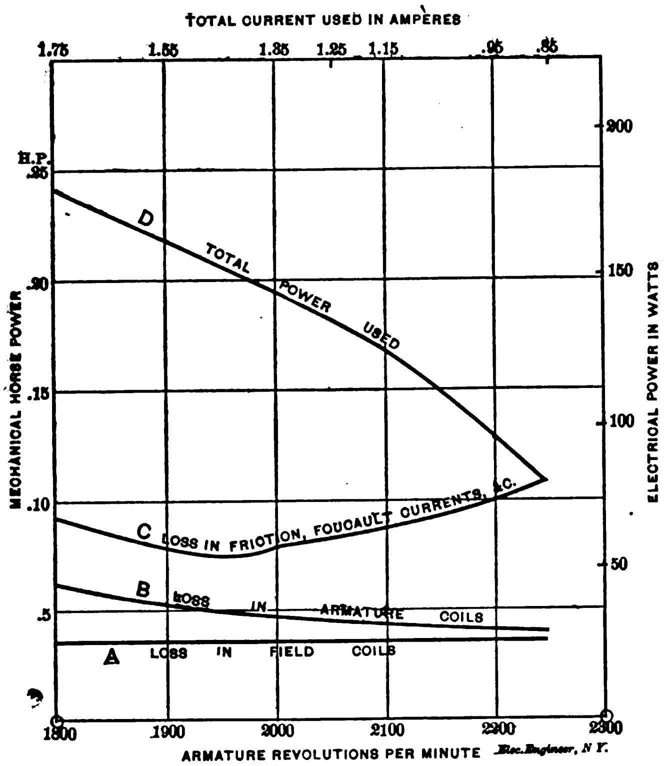

FIG. 2.

The useful power of the motor is represented by the vertical distance between the lines C and D; this power is, of course zero when the machine is running free at 2,250 revolu,tions, and is a maximum of 1-6 h. p. at 1,800 revolutions. This useful power, it will be seen, forms a large part of the total power consumed; in other words, the actual efficiency is high, being 62 1-2 per cent. at 1,900 revolutions when developing over 1-8 h. p.

These figures are good for a small motor, though, of course, 5 or 10 h. p. motors will run up to 90 per cent. efficiency with all the losses correspondingly reduced. In this connection we have only to consider what a very low efficiency a 1-8 h. p. steam, gas, or hot-air engine would be likely to give in order to see the very great advantages the small electric motor has over any other small engine.

DOES CURRENT BETWEEN WHEEL AND RAIL INCREASE TRACTION?

BY O. T. CROSBY.

We have not infrequently seen in print and heard in conversation the statement that in electric railways, working on a grounded circuit, there is an increase in the adhesion coefficient over that obtained in steam propulsion, due to the passage of the current through the wheels. To obtain some light on this subject the following experiments were made:

The car used was fitted with two motors of the second type made by the Sprague company. Its total weight was 10,900 lbs. The rail was of the tram type, and, though rusty, was reasonably free from dirt. The wheels showed tires in ordinary service condition. In such case the ordinary coefficients would show a possible tractive effort, before skidding, of 2,500 to 3,500 pounds. As this would have required currents greater than I cared to use, and would, moreover, have exceeded the capacity of the dynamometer at hand, it was determined to skid only one pair of wheels, and to relieve these of a part of their weight. One end of the car was, therefore, jacked up until the springs were almost, or wholly, relieved. This made it impossible to get dynamometer and current readings simultaneously, as had been desired. However, the ammeter and dynamometer were separately compared.

The currents necessary to produce skidding were first observed when the ordinary connection to ground, *i.e.*, through the metal of the motors, truck, wheels and rail, was in position. The connection was then changed, the ground wire being taken directly to the rail, at a point near the grounded terminal of the dynamo. The wheels were thus out of circuit.

As the first position to which the controlling switch can be thrown admits a current of about 50 amperes (one motor in circuit), a graduated resistance was improvised by putting a soldering iron and a tin plate in circuit; these were approached to, or separated from, each other through a tub of water, in the bottom of which lay the tin plate.

The control thus obtained was somewhat irregular, but answered the purpose. The current could be taken up quite regularly from 0 to about 20 amperes; from that value it frequently jumped to about 42 amperes. In such case the wheels always started to skid, whether ground was made through the wheels or directly to rail. When the current could be made to approach 42 amperes through a better gradation, as with intermediate values of 30, 34, 36 amperes, the skidding did not occur until a higher reading was reached—up to 50 amperes. When the jump was considerable, skidding occurred at even lower values than 42 amperes, as is shown in the accompanying table:

Wheels in Circuit.

(1.)	Current.—0	12	16	37..	Here	wheels skidded.
(2.)	“ 0	12	14	37..	“	“
(3.)	“ 0	14	16	40..	“	“
(4.)	“ 0	12	16	42..	“	“
(5.)	“ 0	10	12	42..	“	“
(6.)	“ 0	25	16	40..	“	“

Similar records, up to 12 in number were obtained.

Wheels out of Circuit.

(1.)	Current—0	12	31	16	42..	Here	wheels skidded.
(2.)	“ 0	14	16	18	42..	“	“
(3.)	“ 0	15	34	40	39..	“	did not skid.
(4.)	“ 0	15	42	40	35..	“	“ “

In the last case (4) the rise from 15 amperes to 42 was not as sudden as indicated in the table, though too quick for the recorder to get clear differences. A number of similar trials was made, to the number of fifteen or twenty. In one case of gradual approach up to 40 amperes, without movement of wheels, the controlling switch was thrown into a position giving less resistance in the field; the current rose to 52 amperes, and the skidding began quite vigorously. The change in position of the switch, the current values being such as are here considered, has little effect on the strength of field produced by the three field-coils, the arrangement of which is changed by the switch-movement; saturation having been reached for any arrangement produced by the switch, at lower currents than the effective values, as shown above.

While the sudden current changes might conceal the particular value just sufficient to produce skidding, the existence of the values, 34 and 25 in the tables above, shows that 37 amperes is about the lowest value, if approached with some gradation, that could produce skidding. This is further shown by this record:

Wheels out of Circuit.

Current.—	0	10	15	23	24	25..No skidding.
"	0	12	15	22	20	23.. "

A general conclusion may be stated—that, while the test was not delicate enough to prove that *absolutely no difference* of adhesion exists in the two cases, yet the difference, if it exists, is not worth considering.

Aside from this test, I may say that with nearly the whole of the experience of the Sprague company to refer to, I can recall nothing which refutes the conclusion here drawn. Furthermore, it is to be remembered that up to date the double metallic systems have climbed as steep grades as the grounded systems. In making these experiments it was noted that the slack of the gearing was taken up at from 5 to 10 amperes. When freed from the supporting chocks, the car started at from 10 to 20 amperes, the needle moving so quickly as to prevent accurate reading. When started by man-power, exerted through a dynamometer, the record shows 175 to 210 lbs. pull, varying with slight irregularities in the track (called level, but varying slightly in grade and condition of surface.)

Correspondingly, when the car was held fast by a chain, the dynamometer in the line of pull, a steady current of 14 amperes through the motor produced a reading of 175 lbs. on the dynamometer, showing the true starting current to have been about 15 amperes. As this occurred when the current passed through the wheels, it again shows that there is no appreciable resistance to wheel movement, either as to skidding or rolling on the rail, produced by the passage of the current.

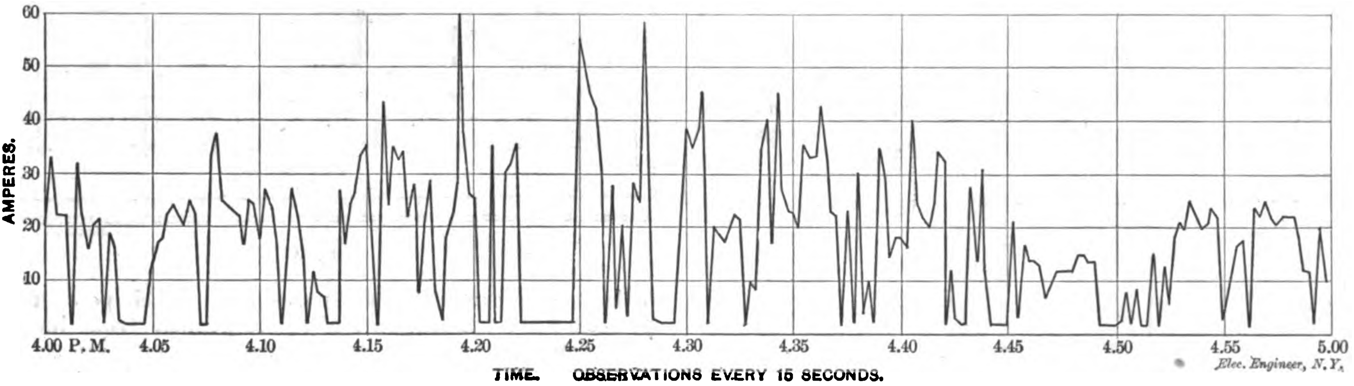
It is to be remembered that the momentary starting current, as shown by an ammeter, is a function, not only of the actual torsional effect required in the motor, but of the total resistance which it has pleased the manufacturers to insert in the motor circuit. Unless controlled, as was here the case, this initial current may, therefore, be greater than *just enough* to start the car.

The writer is indebted to Mr. Offut, superintendent of the Brooklyn and Jamaica Electric Railway, for the use of a car in making these trials.

.... Explanation always progresses by stages; no explanation is ultimate; every explanation is a step up, a removal of a thing from a lower to a higher category.—*Oliver J. Lodge.*

A TYPICAL RAILROAD AMMETER CURVE.

It is evident that in the operation of an electric railway with a large number of cars on the road at one time, there will be frequent stops and starts resulting in a considerable fluctuation of the current on the line. This characteristic has often been commented on but is most forcibly brought out by a glance at a curve representing the readings of the ammeter at the power station. We therefore present to our readers such a curve in the accompanying diagram which records the ammeter reading at the power station of the Sprague electric railway at Brockton, Mass. The curve gives the record for three cars on the road, and brings out very strongly the severe conditions which are met with in this kind of work.



A Typical Railroad Ammeter Curve.

SECONDARY, PRIMARY AND STORAGE BATTERIES.

BY E. R. KNOWLES, C. E.

In all the discussions which have taken place of late, there has been a great deal of ambiguity in the use of the above terms, especially in that of "secondary battery" as applied to storage batteries or accumulators, and it is proposed in this article to attempt to clearly define the difference in the meaning of these terms, from an electrical standpoint.

Looking at the subject of galvanic batteries as a whole, we find a great many kinds of batteries performing a great variety of functions. We have batteries composed of certain substances combined in certain ways, which, when they are put together, are ready, *at once*, without any further preparation, to give off electrical manifestations These are generally known as primary batteries. Some of these when exhausted, can be regenerated by sending through them a current of electricity from some external source. These may properly be called "storage batteries" or "accumulators." Some are not susceptible of any regeneration after once being exhausted and these may properly be called "primary batteries," pure and simple.

Again, we find batteries composed of certain substances combined in certain ways, which are inert in themselves and incapable of giving off any electrical manifestations until further prepared by being acted upon by a current of electricity from some external source. These may properly be called "secondary batteries." They are also, almost invariably "storage batteries" or "accumulators."

Thus we see that we have primary batteries which may, or may not, be storage batteries or accumulators, and we have secondary batteries which are never primary batteries, but almost invariably storage batteries or accumulators; and, conversely, we have storage batteries which may be either primary or secondary batteries.

The writer has ventured to give three definitions, which may help to keep these three great classes of batteries clearly defined and in their proper places, as follows:—

A secondary battery is one which is *inert in itself* and only becomes active to give off electrical manifestations *after* being acted upon by a current of electricity from some external source.

A primary battery is one which is *active in itself* and will give off electrical manifestations *without* being acted upon by a current of electricity from some external source.

A storage battery or accumulator is *any combination*, which will give off electrical manifestations, either before or after being acted upon by a current of electricity from some external source, and which, when it is *exhausted can be renewed or regenerated* by the action upon it of a current of electricity from some external source.

THE NEW WESTINGHOUSE LIGHTNING ARRESTER.

Of the numerous accessory appliances which go to make up a complete system of electric lighting, few have demanded stricter attention and seen greater modifications than the one intended to protect the machine and station apparatus generally from the effects of lightning. The first attempts in this direction copied closely the methods generally adopted for the protection of telegraph and telephone instruments, and consisted of the well-known pair of serrated plates separated by an air space, one connected to ground and the other to the line. When applied to electric lighting, especially high tension circuits, this device was found to be useful only when no current was on the wire; but if the lines happened to be struck during lighting time, with current on the wire, it was soon discovered that the arc formed across the serrated plates by the jumping of lightning charges was maintained by the current generated by the machine. This frequently destroyed the arrester, and also subjected the generators to the liability of a short circuit through the ground.

To avoid this continuance of the arc by the main current, numerous devices have been invented, among them a variety of mechanical contrivances by which, on the passing of a lightning charge, the arrester plates are separated a distance sufficient to break the arc. In another ingenious device of this nature, the arc is blown out by the well-known action of a magnet placed in close proximity to it.

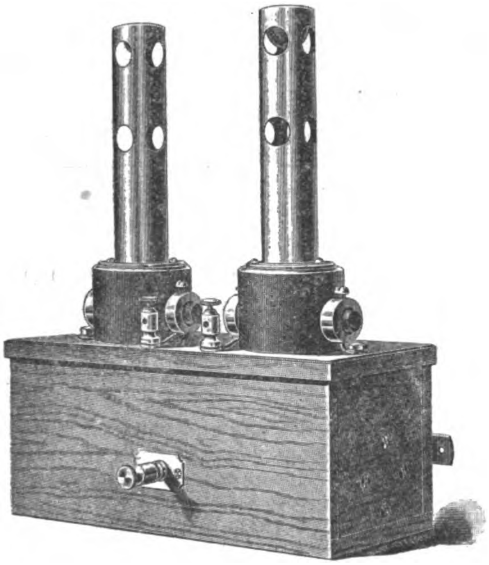


Fig. 1.

That the field in this direction has not been exhausted is evidenced by the fact that still another form of lightning arrester of an exceedingly ingenious nature has been brought out by the Westinghouse Electric Co., the design of which is due to Mr. A. Wurtz. In this apparatus, which is shown in perspective in the accompanying engraving, Fig. 1, the arc may be said to blow itself out.

This will be readily understood by an explanation of the construction of the apparatus which is shown in section in Fig. 2. Here, *a* and *a'* are air chambers separated by a partition. From each air chamber there is a slotted passage *c* and *c'* leading into the tubes *d* and *d'*, the top of each of which is provided with a rubber humper. *e e'*, *f f'*, *h h'*, *i i'*, are ordinary arc light carbons, and *j j'* are carbon balls bridging over the air spaces *k k'*. Each pole of the dynamo has a connection B B' to the ground from its respective binding post on the arrester through *e* or *e'*, *j* or *j'*, *f* or *f'*, *h* or *h'*, the jumping space *l* or *l'*, and thence by *i* or *i'* to the ground binding post.

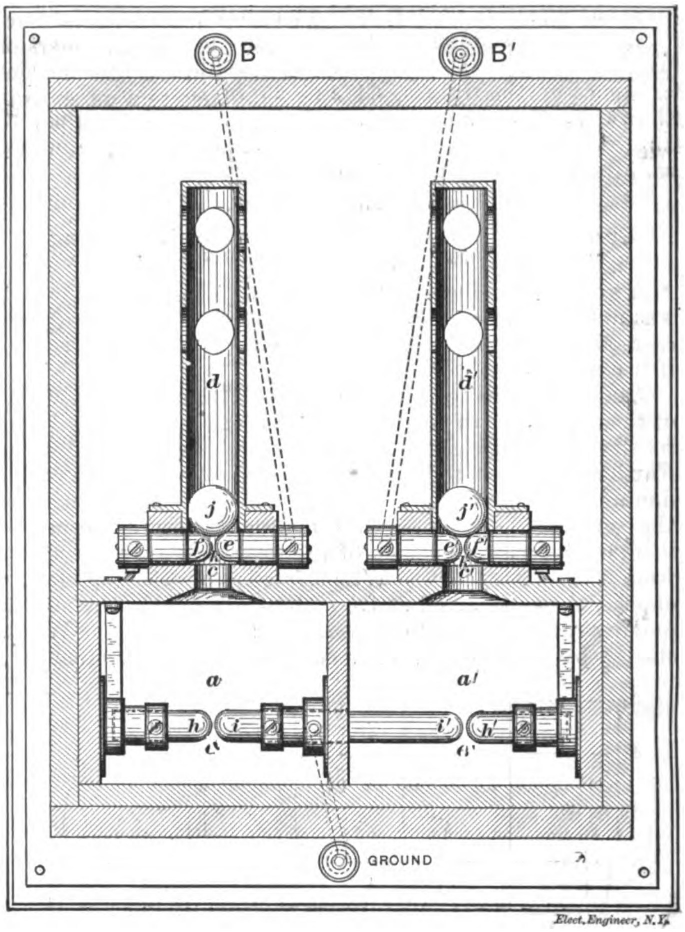

Fig. 2.

The action which takes place on the reception of a lightning stroke is very simple, and is as follows:—

The arc formed at either, or both, of the jumping spaces, *l l'*, instantly heats and expands the air in the respective air chamber, which, rushing up through the passage *c* or *c'*, blows the carbon ball to the top of the tube. The arc formed where the circuit has been broken by the projected carbon ball is at the same time instantly blown out, thus completely rupturing the circuit. The only demonstration is a slight puff as the air rushes out of the holes near the tops of the tubes.

As the carbon balls are confined by the tube, they at once drop back to their former positions and thus automatically place the apparatus in condition to receive another lightning charge.

We recently had occasion to witness the operation of this ingenious arrester, during which, in the absence of an actual stroke of lightning, the jumping spaces *l l'*, were bridged over with a fine wire in order to start the arc. The terminals of the arrester were connected to the circuit of a 3,000 light alternate current machine at 1,000 volts pressure. By the throw of a switch the full pressure of this machine was put on the arrester, and the action of the fusing of the temporary bridge wire, the starting of the arc, the blowing up of the balls and extinction of the arc were so rapid, indeed so instantaneous, that the lights on the circuit showed no flicker whatever.

We may add that the action is so rapid that the carbon pencils and balls show no deterioration after numerous trials.

THE WALKER ELECTRIC METER.

Ever since electric lighting became a commercial success, there has existed a desire on the part of consumers of current to be able to check the amount of the charges made by lighting companies, by reference to a meter, and a variety of forms have been devised with this object in view, and involving many novel and ingenious principles. In seeking to solve this problem in a practical manner, Mr. G. W. Walker has for some time been engaged on the development of an apparatus which embodies several novel features, and the operation of which places at the disposal of the consumer a complete record of the operation of his circuit, and the current consumed. The apparatus may be said to be one in which the current strength is continuously photographed, and the manner in which this is accomplished will be readily understood by reference to the accompanying engravings. The illustration, Fig. 1, shows the meter, which will be seen to consist in the first place of an ammeter coil consisting of a solenoid in which an iron wire in the shape of a nearly complete circle is placed as a core. To the same shaft to which the circle or core of the ammeter is attached there is also fixed a light aluminum sector, provided with a fine vertical slot, and immediately behind this sector is a box which encloses a roll of sensitized photographic paper, and which is shown enlarged in Fig. 2. The screen placed between the sector and the box has a horizontal slot, before which the sensitized roll is made to pass, as will be explained presently. The vertical slit in the sector is so arranged as to come immediately in front of the horizontal slit in the screen, so that in whatever position it may be, it will allow a ray of light to pass from the lamp, shown in Fig. 1, on to the sensitized roll.

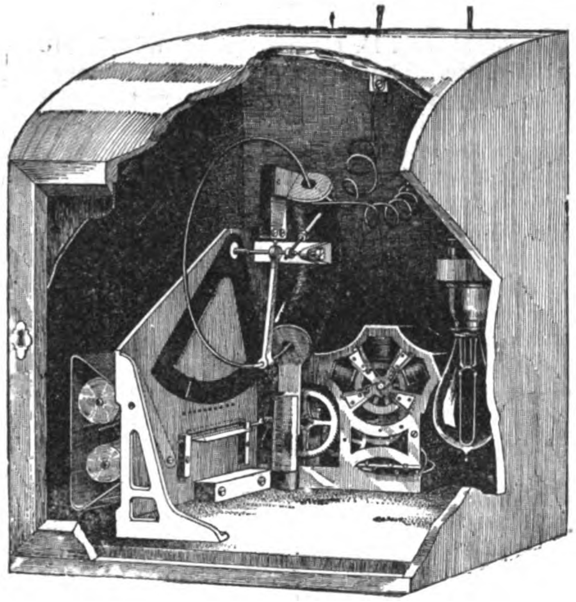

Fig. 1.

In this way it will be evident that, depending upon the strength of the current passing through the solenoid, the sector will take up a corresponding position, which will be indicated by the impression made by the ray of light upon the paper, which will be farther away from the end of the box as the current is increased. It will also be noted that immediately below the slot in the screen is a series of perforations which permit the light from the lamp to pass through continuously, and thus indicate on the paper a continuous series of lines, which, in Fig. 3, are represented by the horizontals shown. The perforations are so placed that each of these horizontal lines represent a certain strength of current in amperes. The movement of the brass sector attached to the ammeter and provided with a slot passing over the horizontal slot in the screen causes the spot of light to record the ampere strength at each interval of time, in the manner shown in Fig. 3.

It is evident, howvever, that some means must be provided for causing a continuous movement of the paper roll, and this is effected by means of a small clock movement which is wound every hour by the small electric motor which is shown in Fig. 1. The clock movement remains stationary when no current is on the circuit, but starts immediately upon the lighting of even one lamp. This clock movement, at intervals of one hour, also turns a shutter and allows the light of the lamp to pass through a slot in the screen, so as to impress upon the gelatine film the vertical lines shown in Fig. 3, and which indicate hours of service. In this way there is impressed upon the paper roll a complete record of the current consumed in the circuit.

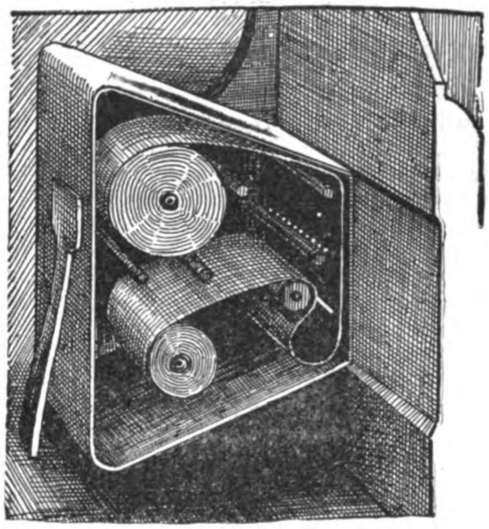

Fig. 2.

This roll, after a certain time, say one month, is taken from the box and developed so as to fix the light impressions, and can then be measured up in the same way as an indicator card, and the current consumed calculated at once. The consumer is, therefore, at any time, able to check the charges made. The entire apparatus is enclosed in a very small space, and the current consumed by it in its operation is only a fraction of that required by a single lamp, $\frac{3}{16}$ of an ampere being sufficient to set the apparatus in operation.

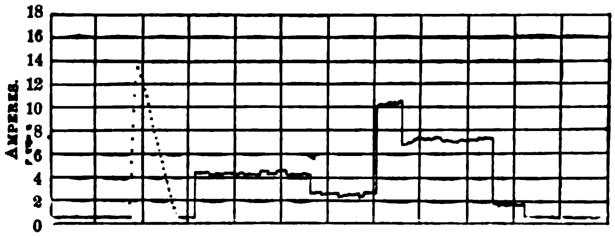

Fig. 3.

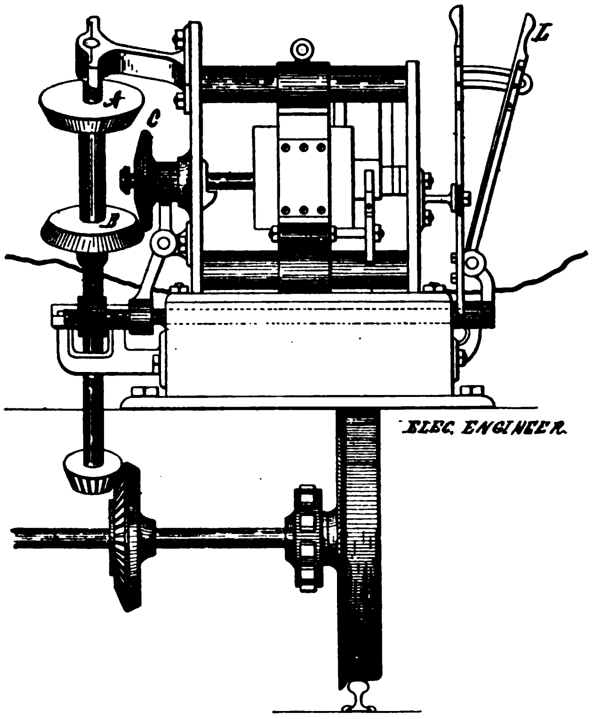
The instrument, while having no delicate parts, is quite accurate, and in a recent test of the same made by Mr. Geo. B. Prescott, Jr., the indications of the meter were compared with a carefully standardized Weston ammeter reading to hundredths of an ampere, and it agreed remarkably well both on rising and falling currents. The tests extended through the full range of the instrument, and the load was varied by single lamps taking from $\frac{35}{100}$ to $\frac{42}{100}$ ampere each, these small differences being distinctly recorded. This accuracy of indication is, no doubt, due to the fact that the recording is done in the manner shown, thus eliminating all friction due to marking points, and the core being relieved of all mechanical work.

We may add that the meter, which is manufactured by the Walker Electric Co., of this city, will be still more simplified by the substitution of a vibrator for the motor which winds the clock movement.

HENRY'S DRIVING GEAR FOR ELECTRIC CARS.

One of the first in this country to take up the subject of electric railways from a practical standpoint was Mr. John C. Henry, who in the early part of this decade operated a short experimental line at Kansas city. From the very first Mr. Henry has been a staunch advocate of the practice of supplying the car with but a single motor and, what is still more important, arranging it so that the motor shall be kept in continuous operation at the same speed, no matter at what speed the car might be running. By this method of operating, Mr. Henry reasoned, the motor would always be working at the maximum efficiency for which it was designed; while at the same time it obviated the difficulties met with in the case where the motors are continually started and stopped with the cars. One of the ways in which this is carried out by Mr. Henry is shown in the accompanying illustration, and will be seen to consist in the application of friction gear. The driving disc C is continuously revolved by the armature shaft of the motor and by means of the lever L can be thrown into, or out of, contact with the discs A and B. The latter are also controlled by a lever and drive the car in either direction according to which one is placed in contact with the driving wheel.

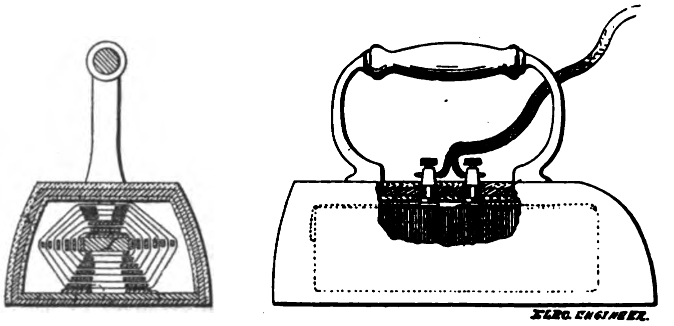


Henry's Driving Gear for Electric Cars.

In a recent patent, in which he describes this arrangement, Mr. Henry also shows an early method employed by him for maintaining contact between the trolley and the overhead conductor, consisting of wheels having grooved faces and held by spring pressure against the sides and bottom of the conductor.

AN ELECTRIC FLAT IRON.

The heating properties of the electric current have already been applied to a variety of purposes in the arts, the most prominent of which is the electric welding method developed by Professor Elihu Thomson. But it seems that in household purposes also, this property of the current is destined to play a prominent part. Electric cooking utensils of various kinds have been designed, and in some instances put into practibal operation. One of the latest novelties in this respect is an electric flat iron which has recently been patented by Messrs. H. R. Butterfield and W. Mitchell, of Waterville, Me. The apparatus, which is illustrated in the accompanying engravings, is so simple as to hardly require more than the briefest explanation. It consists of a hollow flat iron, in the interior of which a coil is placed which is heated by the current passing through it. The ease and comfort derived from the use of such a device, in hot weather especially, is apparent.



An Electric Flat Iron.

DEATH BY ELECTRICITY.

BY OTIS K. STUART.

The recent discussions, which have been prompted by the passage of the new execution law in New York state, upon the qualifications, so to speak, of electricity as a killing agent, have suggested certain opinions as to the manner in which death is produced by this agent; and these opinions have been aired in the columns of many journals both electrical and otherwise. The variety of the opinions, and of the manner of forming and stating them, shows a sad lack of true scientific method in the investigations of those who hold them; for there is apparent an almost entire and universal misapprehension of the nature of the problem involved.

The object of this paper is to present to electrical men a view of the problem, and to point out the manner in which it must be *attacked* if solution is desired.

Life in the animal organism is the result of a continual effort, by certain elements of known chemical affinity, to seek equilibrium by combining, counter-balanced by the continual tendency of environment to overcome or destroy this equilibrium. A muscle in performing its function gives off energy; this energy is derived indirectly from the outside world; but directly it is the result of a disturbed balance in the equilibrium of the elements composing the muscle. The same may be said of any of the organs of the body—the brain, the stomach, the entire nervous system. That this is so, will be clearer if we examine more closely the actions of one of these organs, say, the nervous system, from the beginning to the end of a performance of a function.

In the first place, it will be noticed that in order that function may be *started*, some stimulus must be made to act upon the organ,—the possible exciting forces, in the case of the nervous system, being numerous. For example, we may mention motion or mechanical irritation, change of temperature, electricity, light, odors, sound, etc. These forces *must* act as stimuli upon the nervous organism by some property which they have in common; and, as Mr. James Hinton says,[1] it is hardly possible to conceive this common property to be other than the power which they all and each have of "disturbing an unstable chemical equilibrium." This action of the stimuli, therefore, results in a chemical change in the make-up of the organism, as is proven by the fact "that the same stimulus will not reproduce the effect until after the lapse of a certain interval." The organism must be supplied with those elements which will restore it to its former condition of equilibrium, and *time* is necessary. This chemical change which generally is at the start local—at the surface of the body—is propagated along the nerve as a current, or produces a current of motion, so to speak, in the nerve, which constitutes its *function.*

In health, therefore, the normal equilibrium is easily destroyed; but it is as easily restored. Stimuli act powerfully and at once in the healthy organism, and so do the forces which tend to restore balance—the forces of nutrition which are also *chemical.* Contrari-wise, sickness is that state of an organism in which equilibrium is not restored soon after it is destroyed by the operation of function or of the stimuli which produce function. Sickness must be the result either of *over-sensitiveness* of the organism or of relative weakness of nutrition, or of both; and death results when either one or both of these causes become so powerful as to permanently destroy consciousness and vital power.

If this dictum is correct, any one of the above-named forces, if exerted with sufficient intensity upon the organism, must be capable of producing death; and I think every person will be able to enumerate at least a serious illness resulting from each of the causes mentioned. Vomiting is sometimes caused by the bad odor of a substance, and in certain cases is so violent as to cause serious illness, even death itself; high temperatures, or low ones, produce affections, both local and in the entire system; electricity produces paralysis, unconsciousness and death; tremendous explosions—sound—frequently destroy the sense of hearing, and sometimes occasion permanent mental disturbances; and it is well known that sudden or intense light will cause blindness, while little light or comparative darkness will increase in a painful degree the sensitiveness of the retina.

The conclusion we reach in regard to electricity is, therefore, that it is simply one of the many agents or forces which affect the animal organism, even unto death, by the known power it has of promoting chemical change, or, which is the same, the power it has of destroying one chemical equilibrium to establish another.

This does not solve the problem, for electricity affects other portions of the animal organism as well as the nervous system. It will affect muscular action directly, that is, without the medium or use of the nerves; and, in fact, does so with great power, as will be seen by the fact that it considerably hastens the decomposition of animal matter after death. It will make the "hair stand on end!" But, aside from this, the problem will not be completely solved until, as is evident, those chemical changes produced in the organism by the force of the current are understood. Indeed, not even then will solution be complete; for we will still be ignorant of the manner, the method by, or in, which these changes affect the *vital* functions. But that this is the line of investigation which will lead to the ultimate solution of the problem is, I think, beyond dispute. It is a problem in physiological chemistry, pure and simple.

.... **There** is much pleasure and some profit to be got from tinkering among models when we are boys, but when a young man has chosen a trade or art, he can only learn that trade or art by working under the actual conditions of that trade or art.—*Fleeming Jenkin.*

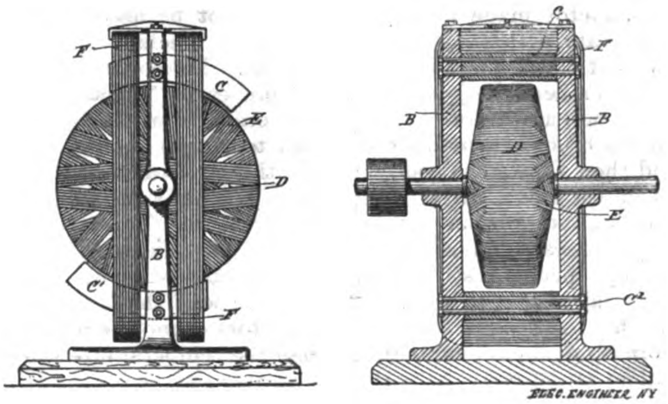
A NEW TESLA ALTERNATING MOTOR.

Our readers are already acquainted with the Tesla alternating current motor, which has now gone into practical application, and the operation of one type of which is based upon the fact that when an alternating current is passed through the coils of such a motor, the field magnets or poles do not appear to manifest their attractive effect upon the armature simultaneously, the magnetic attraction of some appearing to lag behind that of others, with the result of producing a torque and rotation of the motor.

Mr. Tesla has, however, developed another form of these so-called "magnetic lag" motors, but in operation it differs from those just described, in that the attractive effects or phases of the poles, while lagging behind the phases of current which produce them, are manifested simultaneously and not successively.

The manner in which this is carried out, is shown in the accompanying illustrations, Figs. 1 and 2, which represent respectively an elevation and side view of the motor.

As will be seen, the motor has two laminated magnetic pole-pieces C C′ of soft-iron or steel. The laminated disc-armature D is mounted between the pole-pieces C C′, which are curved to conform to the circular shape of the armature. The latter is provided with a closed coil winding. The main energizing coils F F are arranged so as to include within their magnetizing influence both the pole-pieces C C′ and the armature D, the pole-pieces C C′ projecting out beyond the coils F F on opposite sides, as shown.



Figs. 1 and 2.
New Tesla Alternating Motor.

If an alternating current be passed through the coils F F, rotation of the armature will be produced, and this rotation is explained as follows:—

An impulse of current in the coils F F, establishes two polarities in the motor. The protruding end of pole-piece C, for instance, will be of one sign, and the corresponding end of pole-piece C′ will be of the opposite sign. The armature also exhibits two poles at right angles to the coils F F, like poles to those in the pole-pieces being on the same side of the coils. While the current is flowing there is no appreciable tendency to rotation developed; but after each current impulse ceases or begins to fall, the magnetism in the armature and in the ends of the pole-pieces C C′ lags or continues to manifest itself, which produces a rotation of the armature by the repellent force between the more closely approximating points of maximum magnetic effect. This effect is continued by the reversal of current, the polarities of field and armature being simply reversed.

One or both of the elements—the armature or field—may be wound with closed induced coils to intensify this effect. Although in the motor shown there is but one of the fields, each element of the motor really constitutes a field, wound with the closed coils, the currents being induced mainly in those convolutions or coils which are parallel to the coils F F.

Mr. Tesla has designed various types of motors on this principle, among them one having a number of fields, which is particularly adapted to a rate of alternations corresponding to those now in general use on alternating circuits.

DETERMINING THE SIZE OF WIRES FOR RHEOSTATS AND REGULATORS.

There are few electric circuits, whether intended for light or power, which do not require regulation of some kind, and the calculation of rheostats or regulators to effect this frequently enters into the determinations of the electrical engineer. Very few reliable data, extending over a wide range, have been forthcoming on this important subject up to the present, and our readers will, therefore, be interested in the tables recently given by Mr. A. B. Herrick, in *The Electrical World*, which, as we happen to know, are the result of a large and varied practice in the construction of regulators of all kinds.

There are a number of ways in which resistance wires may be mounted; but the method most universally used is to wind the bare conductor in such lengths as required on a mandril; the spiral is then slipped off and slightly stretched to separate the different convolutions. Evidently a conductor made up in this way cannot be used at any temperature that will sensibly affect its mechanical properties of elasticity and tensile strength. Moreover, at such high temperatures oxidation is more easily effected and the conductors more rapidly deteriorate from this cause. Metals brought a number of times to a high temperature and then allowed to cool, which is the practical condition when used as a variable resistance, gradually disintegrate and lose their fibrous or crystalline structure. This is especially noticeable in high resistance alloys. In addition to this the specific resistance of the conductor is increased by being raised to such high temperatures. (See Table I.) These are the practical reasons why conductors cannot be used at more economical temperatures than the temperatuure they will be raised to by the current in amperes given for the different metals and diameters in Tables No. II., No. III. and No. IV. These tables have been figured from actual experiments made under practical conditions. In column No. 1 of each table is given the capacity in amperes of galvanized iron wire, tinned iron wire and German silver wire wound in spirals and mounted in wooden boxes, where fair ventilation is given. The current capacity of these wires is the maximum that should be allowed where wood or combustible material is used in construction.

TABLE I.

Iron wire. Temperature.	Resistance.	Copper wire. Temperature.	Resistance.	Platinum wire. Temperature.	Resistance.
0° C.	640	0° C.	814	0° C.	1,870
21° C.	691	21° C.	864	21° C.	1,986

Dark grey	2,460	Brick red	3,300	Light red	5,050
Scarcely incandescent.	3,050	Bright red	4,700	Orange	5,400
Dark red	3,200	21° C.	910	Light yellow.	6,000
Bright red	3,650			21° C.	1,984
Red hot	4,550				
White hot	4,880				
21° C.	727				

A spiral loses its heat by convection much more rapidly in a horizontal than in a vertical position, and it will always be advantageous to design the resistance box so that when in use the spirals will be in a horizontal position. The box or frame in which these spirals are mounted should be open on the sides to admit free access of air.

In using columns No. 1 in the Tables Nos. II., III., IV., the wires can be used at the amperes capacity given, independent of the size of the box, and the total number of watts lost in the regulator.

Columns No. 2 give the amperes that can be carried by these wires where fire-proof construction is used. Columns No. 3 give the capacities that can be used for the special purpose of starting shunt wound motors. The amperes given are the currents which the wires will stand for one minute, and as forty seconds is ample time to start a motor under full load, the factor of safety is such that the wires would be brought only to a very dull red if by accident the starting

coils were left in circuit. These capacities are only to be used with fire-proof construction.

In column No. 1, when the wire is mounted in a wooden box, with fair ventilation the heat limit is found to be 39 degrees Cent. In column No. 2, with fire-proof construction and with slate or porcelain used as an insulator, and with free access of air, the heat limit is 48 degrees Cent., the temperature of the surrounding air being 22 degrees Cent. In column No. 3 the temperature attained varies as the time during which the current is passing through the wire, the maximum being about 400 degrees Cent.

In the case of galvanized iron wire table, the Washburn & Moen gauge is used, as by this gauge this wire is most readily obtained in the market. The wires on which these resistances were figured is on what is known as grade "B," one mil-foot being equal to 92.6214 legal ohms at 15.50 degrees Cent. This wire has a resistance about 8 per cent. higher than the best grade of galvanized iron wire used in line construction. The resistance per cubic centimetre will vary from 1 to 1¼ per cent., depending upon the per cent. of carbon in the iron and the thoroughness with which the galvanizing has been done. At a temperature of about 18 degrees Cent. the resistance increases about .41 of one per cent. for each degree. If any greater degree of accuracy than 1¼ per cent. is required, a sample of the wire to be used in the construction of the resistance should be tested for its conductivity. Resistance in the tinned iron wire table was determined from ordinary tinned iron wire. The resistance of different samples may vary about 1½ per cent. from that given in the tables.

It will be noticed in comparing the different tables that different wires carrying the same amperes have all about the same resistance per foot; there is a slight difference in favor of galvanized iron wire, which may be accounted for by the zinc covering radiating more readily than the bright surfaces of tinned iron and German silver wires.

The formulæ which agree most closely with the curve plotted between ampere carrying capacity and diameter in mils to bring the wires to the temperatures given were in column 1, $c = .012\,d^{3/2}$; in column 2, $c = .014\,d^{3/2}$, and in column 3, $c = .031\,d^{3/2}$, and also in column 3 the heating effect on the wire will be found to correspond very closely with the specific heat of iron as given by Tyndall, that 2,000 foot pounds are required to raise one pound of iron from 0 to 100 degrees Cent. The high specific heat of iron is of great advantage in the case of starting shunt wound motors, as a large amount of energy disappears in raising this wire to a high temperature.

RESULT OF THR PARIS ELECTRIC METER COMPETITION.

In the month of March of last year, as our readers are aware, the city of Paris organized a competition and offered various prizes for electric meters, with the object of adopting the best for use on the circuits supplied by the electric lighting stations operated by the city. This competition was entered into by a number of inventors, and the report of the committee who made the tests upon the various meters submitted, has just been rendered. The number of competitors entered was 28, and included all the best known meters now in existence.

The results attained by the committee were such that they were constrained to report that none of the meters was of sufficient merit to warrant the award of the prize of 10,000 francs for the best, nor that of any of the other prizes designated in the original articles of the contest. But among those submitted a number had exhibited such merit as to entitle them to recognition, and, in accordance therewith, the committee recommended the granting of the following sums: 2,000 francs to M. Cauderay, 2,000 francs to M. Aron, and three sums of 1,000 francs each to MM. Brillié, Blondlot and Jacquemier.

As the competition did not accomplish the object for which it was instituted, due partly to the shortness of the time given to inventors to prepare for the same, a new competition has been organized, of which the following are the conditions:

ELECTRIC METER COMPETITION FOR 1890.

1. The competition will be open to all inventors of electric meters or registers applicable either to continuous currents only, to alternating currents only, or, simultaneously, to both forms of current.

2. The apparatus submitted may be ampere-hour meters or watt-hour meters.

3. The meter ought to be direct reading and have an integrating device of such a nature as to show at once the total current consumed.

4. Meters ought to be able to register at very small currents; the quantity meters ought to start with $\frac{2}{10}$ of an ampere, and the energy meters at 20 watts.

5. The meters, accompanied by an explanatory note, must be deposited in a sealed package at the Hotel de Ville at the office of the "Sous-Directeur des Travaux," Paris, before the 31st of August, 1890, at the latest.

6. The meters presented will be submitted to the judging of a Committee of nine members, five of whom will be designated by the Municipal Council, and four by the Administration.

7. The apparatus will be submitted to the following comparative tests: Their exactness over the whole scale for which they are designed; their practical value as regards regularity of operation, simplicity, cost, etc.; the energy consumed by them during operation; the attention required by their employment in the distribution of current.

8. The sum of 18,000 will be distributed under the following conditions: 10,000 francs to the inventor producing a meter giving every satisfaction and applicable equally well to alternating and continuous currents. In case the meter can only be applied to one of these two currents, the inventor will be entitled to one-half of this prize. Prizes amounting to 2,000 francs to meters destined at the same time for alternating and continuous currents, and 1,000 francs for meters applicable only to one of these two currents will be distributed to inventors whose apparatus indicates important progress.

.. THOSE who take part in the endowment of research are the truest and greatest of modern philanthropists.—*Professor Robert H. Thurston.*

. .. THE mechanic well knows that absolute truth is unattainable, but he nevertheless values highly the approximation to truth which allows him approximately to ascertain the result of given simple material combinations.—*Fleeming Jenkin.*

.... To Faraday the space round conductors was full of what he called lines of force; and it is his main achievement in electrostatics to have diverted our attention from the obvious and apparent to the intrinsic and essential phenomena.—*Oliver J. Lodge.*

.... THE subject of thermo-electricity has been eclipsed by the magnificent development of the dynamo-electric machine, but we may yet return to thermo-electricity as a practical source of electricity.—*Professor John Trowbridge.*

.... LET us *make* a place for physical science in our lowest schools and give to every pupil, every boy and girl in the land some knowledge of physical forces. Above all, let the lesson of conservation of energy be drawn from the various familiar cases of its transformation.—*Professor W. A. Anthony.*

PHENOMENA OF ALTERNATING CURRENT INDUCTION.[1]

BY PROFESSOR ELIHU THOMSON.

About three years ago I had the pleasure of bringing to the attention of the American Institute of Electrical Engineers at its annual meeting, certain phenomena of the repulsive action between conductors such as coils of wire traversed by alternating electric currents. It was then noted that if such a current be sent through a circuit wound as a coil, and either provided with an iron core, or not so provided, and permitted to induce in another coil or circuit, a current under conditions which allowed a lag or displacement of phase of the latter from its theoretical position, a repulsive effort would be exerted, tending to remove one coil from proximity with the other, or to deflect one of them to a position such that the plane of the coils would be at right angles,—one to the other.

Many modifications of the arrangements of the coils were described and apparatus based upon the principle of inductive repulsion, as I called it, were touched upon. I need not now enlarge upon these matters. It may suffice to say that current indicators and potential indicators or voltmeters have been constructed embodying the principle as applied to the quantitative measurement of alternating currents. Arc lamps have been made in which the regulation of the carbons has been effected by the repulsive action of a coil traversed by the current fed to the lamp, or by a derived current around the arc, acting on a closed band or circuit movable with the regulating and feeding frame of the lamp. Various forms of alternating current motors have been made in which the revolving portion is composed of coils arranged to be closed upon themselves, and inductively acted upon by the currents in what may be called the field or inducing coils connected with the alternating current source. The principle has been applied in other apparatus, such as regulating mechanism for alternating currents and in electric meters.

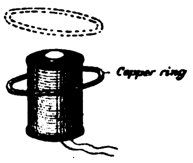

FIG. 1.

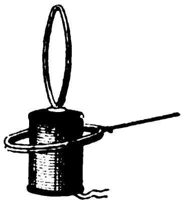

FIG. 2.

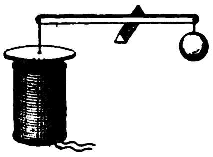

FIG. 3.

It is my purpose this evening to bring before the Institute some experimental apparatus showing the action of inductive repulsion in some of its phases; following this by a brief account of a number of other effects somewhat allied to it, with experimental demonstrations of the same. Some of these experiments were to be seen at the Paris Exposition of last year in connection with my exhibit there, and others of them are more recent still, while still others have never been shown at all in public. The field is a fruitful one, and there is not time to touch upon other than the more striking, and perhaps interesting, phases of the actions exhibited, which are susceptible of modification to a great extent by changes in proportion and arrangement of apparatus.

I may here revert to one experiment which is almost a repetition of one I made about five years ago. If a copper disc or closed coil be balanced in front of another coil and parallel thereto, it will be noticed that on passing a current into the second coil, the disc or closed coil will be repelled slightly, and if the current be afterwards shunted or cut off, there will be a slight attraction. By opening and closing the shunt so as to put the current successively on and off the coil, there will be alternate repulsions and attractions exhibited. Let the current, however, be so put on and off very quickly and the attractive effect will become less than the repulsive effect, and the disc or closed coil will be driven away or bodily repelled. Replace now the intermittent current by an alternating current which reverses many times per second and the repulsive effect alone is noticed, provided that the disc or closed coil is of sufficient mass and conductivity to allow currents of high self-induction to be set up in it, whereby such disc or coil or current in it may, as it were, exert a controlling influence upon the magnetic field in immediate proximity to it.

The amount of this repulsive effect may, under favorable circumstances, become so great as to give with moderate current densities a very considerable pressure or force.

I have selected some particular instances of this action for our experiments, as it will be understood that time is too short to show many variations of the effect as found in numerous experimental trials.

Placing a copper ring over a coil which has been wound upon an iron core, and passing an alternating current through the coil, gives so much repulsive effect that the ring is thrown forcibly away and up into the air (Fig. 1). Or, again, the ring may be supported for a moment in free air, though its condition is one of unstable equilibrium. Further, we may arrange a string or thread to so guide the ring that it cannot move laterally though free to fall towards the alternating current coil (Fig. 2). It is in this case supported in the magnetic field of the coil and away from it. It takes a position of balance between the repulsive effect and its own weight, which are opposed forces. As a curious variation, another copper ring (Fig. 2) may be added under the former, to which it seems to be attracted as though magnetized, after which both rings are supported as one. The explanation is very simple. The currents induced in both rings are in the same direction at any instant and produce attraction. The bearing of this will be seen in later experiments where rotary actions are produced.

Copper plates are but imperfect discs and act as closed coils. Aluminum rings, having much less weight than copper, might at first be expected to be more readily supported, but it must be remembered that the conductivity of aluminum is much less than that of copper, and hence that since the effect depends on current induced and retardation of phase or lag of such current, copper is the better on account of its high conductivity.

By attaching the closed ring or coil to a balance beam (Fig. 3), we are able to measure the amount of force exerted with different currents, and different materials or constructions.

Such measurements show very decidedly that the repulsive effort depends on the strength of the current in the inducing coil, and in the ring or closed coil, and on the relation of the position of the waves of induced current in the closed coil or ring with those of the inducing current. The effects are, properly considered, magnetic repulsive effects of the opposing fields of the induced and inducing currents relatively.

When the closed coil or disc is mounted so that it can only turn on an axis in its plane then the repulsion resolves itself into a deflection of its plane to a position at right angles to the plane of the inducing coil, or, more strictly, to parallelism with the direction of the magnetic lines set up by such inducing coil. The effect of the control exhibited by such a closed circuit of good conducting power over the magnetic field of the inducing coil, is seen by interposing such closed circuits between the inducing coil and another coil acting as a secondary and feeding an incandescent lamp (Fig. 4). The light of the lamp is cut down and extinguished thereby, as the alternating field is now almost completely shielded from the secondary. The coil feeding the lamp undergoes a slight repulsion. This is easily exhibited by placing in a glass jar with water a lamp and coil, the lamp wires being connected with the coil terminals, and so loading it that it just sinks to the bottom of the jar. Placing this above the inducing coil so as to bring it into the alternating magnetic field, is attended not only with the lighting of the lamp under water, but there is noticed a repulsion or floating of the lamp to a certain point (Fig. 5), at which its tendency to sink just balances the repulsion exerted. So long as the lamp remains so suspended in the water its brilliancy is constant, notwithstanding that the strength of the inducing current be raised or lowered considerably. It is of course, unnecessary to use water to balance the lamp coil, a beam and counter-poise weight will suffice (Fig. 5a).

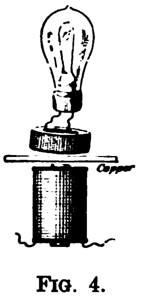

FIG. 4.

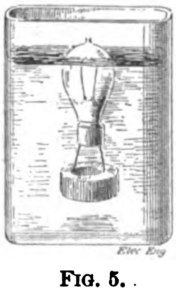

FIG. 5.

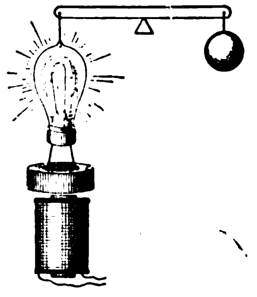

FIG. 5*a*.

In utilizing the repulsive action for obtaining movement from alternating currents, the closed coil or circuit may be mounted in various ways.

A convenient form is one in which a bent core of iron wire or plates which may be a ring is wound over with insulated wire at a portion only of its surface. A closed band or secondary is pivotally mounted so as to pass over the curved core and also over the wire covered portion if moved around the pivot by a suitable carrier (Fig. 6). A spring or weight may tend to cause the closed band to pass over the wire-covered portion of the core. Currents sent in the wire coil produce repulsion and movement of the closed band about the pivots to a position on the core removed from the coil.

This apparatus, and some of its modifications, is a valuable reactive coil which gives a smooth variation and hence is called a "smoothly acting reactive coil," for it enables us by changing the relation of the closed band or secondary circuit to affect the inductive resistance, as it may be termed, or the impedance of the coil wound on the core; the changes being made by swinging the closed band on its pivotal support by a suitable operating handle. It so varies the effects in an alternating circuit as to represent those of variable resistance in a continuous current circuit, but it does this without much loss of energy, and not by steps but through the finest gradations. The power is greatly increased by the provision of a movable iron armature for the core, centrally placed and pivoted, carrying the closed secondary coil upon it.

---

[1] Abstract of a lecture delivered before the American Institute of Electrical Engineers, at Columbia College, April 2, 1890.

It is easy to see that by placing on a laminated armature core a series of coils which can be suitably short-circuited by a commutator and placing such armature between poles of alternating magnetic polarity, or, better, surrounding such armature by coils for producing directly in it an alternation of magnetic states, while the magnetic circuit is completed by an outside magnetic circuit of laminated iron, we have obtained a rotary motor for alternating currents which may be termed a transformer-motor, since the armature currents are induced and not obtained from the outside.

But by properly constructing such a machine it is not necessary to have a commutator if we are content to start the motor initially by some means, for we may close the armature coils on themselves, pass alternating current through the field coils so as to establish an alternating field in which the armature exists, and it will be found that the machine will turn in the direction in which it has been started and run up to a speed depending on the construction. I have constructed a number of such machines, some of which are self-starting without a commutator. They are made self-starting by special features of construction. Whether they can be made of high or fair efficiency remains to be seen. Using only one alternating current, they can, of course, be used on existing lines.

There are a number of curious effects to be described which depend on a shifting or propagation of magnetic lines of force. Many of these effects were worked out conjointly by Mr. M. J. Wightman and myself, and some of the ways of exhibiting them are due to the skill of my workmen carrying on the construction of apparatus.

The principles may be briefly stated as follows:

1. If two or more closed circuits are similarly affected inductively by an alternating magnetic field, they will attract one another and tend to move into parallelism.

2. Iron or steel masses placed in an alternating magnetic field give rise to shifting magnetism, or lines of force moving laterally, and may, therefore, act to move closed circuits in the path of such shifting lines.

8. Closed circuits in alternating magnetic fields, or fields of varying intensity, give rise to shifting magnetism or lines of force moving laterally to their direction and may, therefore, act to move other closed circuits in the path of such lines.

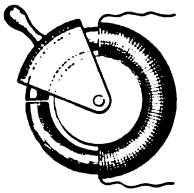

FIG. 6.

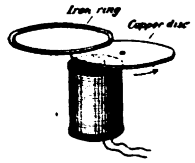

FIG. 7.

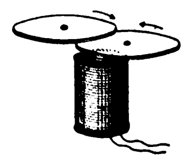

FIG. 8,

4. Iron or steel masses may, when placed in an alternating magnetic field, interact with other such masses, or with closed electric circuits so as to produce movement of such masses or circuits relatively, or give rise to tendencies to so move, the effects depending on continual adaptations of shifting magnetism and retained magnetism relatively.

The experimental demonstration of these principles can be carried out with very simple apparatus. The explanations of the actions which occur in accordance with known principles are in many cases very evident and in others are arrived at with a little study. Nevertheless, the experiments illustrate in a marked manner properties of matter and peculiarities of magnetic action which will probably never be fully understood unless the nature of the ether and its relations to what we call matter are discovered.

We will return to the case of the ring attracting another ring to it. Here we have the case of like currents in parallel direction producing attraction. Such an action can be made continuous. We have only to place a ring or plate over the alternating current coil or pole of its core and then bring a copper disc free to revolve on pivots into proper position relatively thereto. This can best be done by placing the ring or plate so as to be somewhat to one side of the pole, so as to shade it in part, as it were, while a part of the pivoted disc is placed under it, or over it, in front of the alternating field pole (Fig. 7). The disc then revolves from the unshaded portion of the pole towards the shaded portion where the closed ring or plate is placed.

The actions are due to lines of magnetic force at each alternation of current in the magnetizing coil below meeting a retarding influence or opposition to their development over that part of the pole shaded by the copper ring or plate, owing to currents induced therein. The copper disc is the seat of similar currents, but chiefly about those portions not shaded by the ring or plate. Owing to self-induction these currents in ring and plate tend to persist into the period of reversal of the field. This gives rise to a movement of those portions of the disc where current is flowing into a position directly adjacent to the ring or the currents flowing in it, an action which is repeated at every alternation and results in a revolution of the disc. While this explanation is probably the simplest it must be borne in mind that it is but an expression of a set of magnetic actions or changes in the magnetic field; such magnetic field being the resultant of the changing force of the original alternating inducing field and of the magnetic effects of the currents set up in the ring or plate and the disc, both of which latter have a retarding action due to self-induction of the currents in them.

If now two discs be used instead of one (Fig. 8), it will be found that they may each shade a portion of the pole and that the discs, if made to overlap, will both revolve in opposite directions relatively.

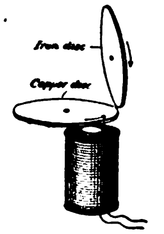

FIG. 9.

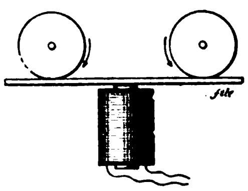

FIG. 10.

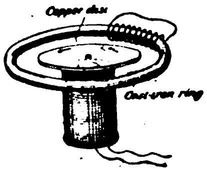

FIG. 11.

An iron disc may be substituted for one of the discs above and used with the fixed plate or ring below it and so be caused to revolve, and its position can be changed so that it is in a plane vertical to the plane of the plate or ring (Fig. 9). Also, it may be similarly used in relation to the revolving copper disc. In fact the positions of two copper discs pivoted so as to be revolvable, or of a copper and iron disc, may be greatly varied and effects of rotation obtained.

If we vary the experiment by placing a closed coil around a part of an iron core upon which is also wound a coil which can be put into an alternating current circuit the effects obtainable are similar to those described above; that is, the structure becomes capable of revolving copper or iron discs held near it. The direction of revolution is such as to indicate a propagation of magnetism or magnetic polarity at a retarded rate through that portion of the iron core covered by the closed coil. In this respect a bar of iron unlaminated or not divided is the same as a core surrounded by a closed coil, for it is also capable of causing the rotation of the discs, when such a bar is abutted to a laminated core alternatively magnetized, or when such a bar is surrounded at part of its length only by the magnetizing coil. A bar of steel substituted for the iron, even if well laminated, is able to cause brisk rotations of the copper or iron discs.

With hardened steel the action is the more marked, a file serving for the experiment. Here the "hysteresis," or coercive force, or magnetic friction, retards the propagation of the magnetic wave. By laying a large file flat-wise against the alternating magnet pole, at about the middle of the file, (Fig. 10), two discs of copper or iron may be kept revolving; or one each of copper and iron held over those portions of the file projecting from the pole of the magnet over which it is laid will revolve. The iron disc may be held vertically and the copper horizontally or flat-wise to the file.

Cast-iron behaves like steel, though more feebly. A ring of cast-iron having a closed coil wound on one part (Fig. 11), can be laid on the pole of the alternating magnet coil and it will rotate an iron disc concentric with it if the placing of the closed coil portion of the ring is not made so as to bring it either over the pole or diametrically opposite that point, the best effect being obtained when it is alongside of the pole.

A small motor of a curious type has been made, utilizing the principle of shading the pole by closed circuits. A laminated ring (Fig. 12), is wound over with wire, but has a slot cut through it dividing the ring and causing it to present two pole faces opposite to each other at the cut part. Each pole is arranged by a set of closed copper bands to be "shaded," as I term it. A copper disc free to turn introduced by one edge into the slot, turns rapidly and exerts some power.

Removing the disc it is found that a silver coin can be inserted into the slot and will be drawn into it and propelled with some force through the same, while a lead coin, or coin of base metal, will be scarcely affected. This is due to the vigorous currents which can exist in the silver, owing to its high conductivity, while the very low effect of the lead is due to the opposite cause.

To obtain a rotary effect on a copper disc we can, however, simplify matters very much by using no closed circuit at all, nor even a steel piece. We may place the disc partly over the alternating pole and then hold over the disc a bundle of iron wires or unwound core, taking care to offset its axes to some extent from that of the pole towards which it and the disc are presented. The result is at once a rapid revolution of the disc in the direction of the offsetting.

The rotary effects are utilized in the construction of electric motors and meters of more or less merit. They are capable of very great variation by changing the forms and relations of the devices used.

Some curious modifications of the effects are found in the revolution of copper balls or cylinders. A hollow copper ball may be laid on a plate of copper (Fig. 13), or within a ring of the same metal and set in gyratory movement, its direction of rotation as well as the position of its axis of rotation depending on the relation of the ball and the plate on which it rests or the ring which encloses it in relation to the alternating pole which is used to set it in movement.

It will even rotate on a horizontal axis while resting on a plate of copper; this requires that it rub its equator upon such surface and overcome the friction.

Placing the ball in a vase of water in which it floats and supporting the vase over the pole upon which has been laid a plate of copper partly covering the pole gives vigorous rotation of the ball in the water. Several balls of various sizes may be placed in the vase or a copper dish substituted for the plate, or the ball and dish both used together (Fig. 14). The effects of these latter are both amusing and instructive.

We need scarcely stop to consider that these actions are brought about just as the movements of the discs were set up by induced currents and shifting magnetic lines that are retarded by the closed circuit currents set up in the plates, rings. etc., which have been employed to modify the field.

But, as we have shown, it is not necessary for obtaining some of these effects that the field be modified by closed circuit currents. Slight changes in the position or shape of parts may be sufficient to give rise to rotatory effects. Thus we may place a cone or wedge of iron on the alternating pole (Fig. 15), and hold near it a copper ring mounted so as to be able to revolve. The ring in this case is best provided with a laminated iron interior which supports it and enables it to be easily mounted on a shaft. The copper cylinder revolves and its direction is such that it seems to be blown around by a blast from the edge of the wedge or point of the cone.

A curious electrical gyroscope is constructed as follows: A vertical pivot projects from the centre of the alternating pole (Fig. 16), upon which pivot is hung a horizontal rod, bearing on one side of the pivot a copper frame, in which is carried a copper ring or wheel with an iron inner portion, such ring or wheel being delicately pivoted in the frame in the usual way. The rod bears on its other end the counterpoise or balance weight. The copper frame bearing the ring is placed in an inclined direction with reference to the horizontal. Under these circumstances, rotation is given by the alternating field in which the instrument is placed, and the properties of the gyroscope are exhibited. It is needless to say that a little ingenuity may modify the instrument in form or lead to the construction on similar principles, of a variety of curious devices, receiving their movements from the actual space, as it were, in which they are placed and without direct connections of an electrical or mechanical character.

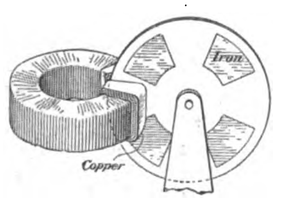

FIG. 12.

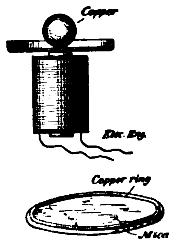

FIG. 13.

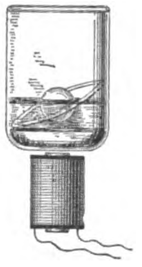

FIG. 14.

There is a growing tendency among electricians to regard the effects of what is called an electrical current in a conductor, to be due, in large part at least, to a movement of particles or to a transmitted strain which has its place entirely outside the wire or conductor, and in the space around such conductor. The wire and current in it, are regarded simply as the central core of a set of disturbances in the medium surrounding it, by which medium the energy of the current is actually transmitted, if the current itself is not merely an effect of such a set of disturbances in the surrounding medium.

Viewed in this light the phenomena we have been considering are seen to be simply the result of modifying these outside effects by conducting or magnetic masses placed in the medium subject to disturbance. The coil conveying the current sets up a changing set of strains in the ether around it, or rather the coil itself is only the centre of such strains transmitted into the medium surrounding the wire from the source of current used, which may be a dynamo located in a central supply station. The changing set of strains around the coil used in the experiments, can set up current in other conductors than the coil subject to their action. Thus are produced the induced currents in the copper rings, balls, plates, etc., used. Such currents react on the medium and modify the distribution of strains, and so give rise to the movements and other phenomena displayed.

The relation which exists between a primary inducing coil and a secondary coil in an inductive apparatus or transformer is of the same nature. The secondary coil is merely a conductor immersed in the medium which surrounds the primary coil. The latter and the wire leading to it from the source of current, is but the core of a set of disturbances or strains in the ether surrounding it, and in which the secondary coil is immersed. Hence the coils, though insulated from each other, are yet both immersed in the medium whose transmitted strains are the real expression of electrical energy transmitted. The result of this relation is, that, were it not for the fact that the coils must necessarily be made of imperfect conductors, the amount of energy transmitted to a secondary coil from its primary could be unlimited,—it might be thousands of horse-power, and the iron core of the transformer be only of such size as to be easily lifted in the hand.

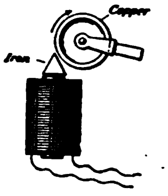

FIG. 15.

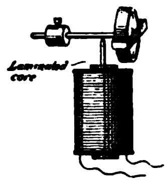

FIG. 16.

Let us imagine the primary and secondary coils of an induction apparatus made of pipe, through which a refrigerant is circulated, or around which a powerful refrigerating action is exerted, such as might be obtained by the evaporation of liquified gases, and in such case the resistance of the coils would become very small indeed. The coils could carry large currents without loss, and the amount of energy obtained in the secondary would almost keep pace with the energy supplied to the primary. A remarkable example of this wonderful capacity for energy transmission, is seen in some transformers for electric welding, in which 20,000 to 30,000 watts, or from 30 to 40 h. p. are transferred to the secondary coil from the primary, apparently, while the iron core or magnetizable core is of quite moderate dimensions. In fact, the iron core has but little to do with the capacity for transmission of energy by induction, though it affects the E. M. F. set up in the turns of wire of the coils.

Could we imagine an open coil without iron, composed of two interwound coils of copper wire or tubes insulated from each other, and kept at the lowest possible temperature so as to practically abolish the resistance of the copper, we would have an apparatus of the very highest efficiency for the transfer of electrical energy from one circuit to another, and one which could be of very moderate size, and yet transfer enormous amounts of such energy, to be used for lighting, metal working or other purpose.

There has only been time in this discussion to touch upon a few salient features of our subject about which a volume might be written at the present time, the object being to bring to the notice of the Institute rather the experimental demonstrations only, stripped of such theoretical considerations as would, if incorporated in this paper, have taken up much more than the space allotted to it and perhaps have exhausted the interest of the hearers.

THE COST OF ELECTRIC LIGHTS IN TOWNS AND CITIES.[1]

BY V. ROSEWATER, JOHNS HOPKINS UNIVERSITY.

QUESTIONS of an economic nature are becoming more and more topics for public discussion. The people, as a whole, are gradually awakening from that lethargy in which they were willing to allow anything and everything to take its own course, regardless of the public convenience. And now, in almost every city in the country problems of rapid transit, adequate water supply, or proper illumination of the streets are claiming the attention of the citizens. Probably no one of the larger cities has yet done entirely away with gas for out-door purposes; but all have, to some extent, made use of the modern substitute. From this the importance of the question whether such lighting should be undertaken directly by the municipal authorities or should be left to private enterprise ought to be clear to every one. Consequently, any investigation which will throw the light of general experience upon the matter should prove of great value and of general interest.

---

[1] *The Independent*.

Some time last fall a committee of the Council of the city of Scranton, Pa., which had been appointed to investigate the matter of electric lighting and the differences which had arisen between the city and the local company, made its report. This committee, "in order to deal intelligently with the question in hand, had deemed it wise to correspond with other cities in the United States, and to gather such data as they might have to furnish for the guidance of their deliberations." The answers received as a result of this correspondence were tabulated for more convenient perusal, and now furnish not only the most complete but also the most reliable statistics upon the subject which have been compiled up to this time. The following table presents the figures for those cities in which arc lights were supplied by contract with private companies. All lamps are 2,000 candle power except in Newburgh, Norwalk, Richmond, Va., Northampton, Mass., Taunton and Concord, whose lights are 1,200 candle power. The area lighted is, in every case, the entire city. In Scranton alone the radius is a factor in the cost:

Name of Place.	No. Lights.	Cost per Annum.	Hours Lighted.
Alliance, O	8	$144 00	All night.
Janesville, Wis	8	100 00	Midnight.
Cedar Rapids, Ia	10	126 00	Except moonlight.
Gloucester, Mass	13	96 00	12 o'clock.
South Bend, Ind.	14	100 00	12 o'clock.
Union City, Ind.	22	95 00	Except moonlight.
Ashland, Penn.	23	125 00	All night.
Keokuk, Ia	24	126 00	Except moonlight.
Ogden	25	133 33	12 o'clock.
Bath, Me	27	100 00	5 all night, 22, 12 o'clock.
Keene, N. H	27	100 00	12 o'clock.
Chattanooga, Tenn	30	121 66	All night.
Wooster, O	30	108 00	All night.
Concord, N. H	39	100 00	12 o'clock.

One need not have much knowledge of the subject to ascertain, by glancing at these figures, that the charges do not conform to the cost of production. The predominance of even figures would point to a merely arbitrary rate, while the partiality shown for a charge of one hundred dollars seems to indicate a desire on the part of the electric lighting companies to keep their books in the most simple manner. Where an odd figure is to be found, it may easily be inferred that the authorities and the company originally failed to come to an agreement. But the company, with great condescension, must have granted a reduction or offered to "split the difference," to which fact may be assigned the frequent form of 2½ or 3½.

A great imposition may be discerned in the relative charges for large and small numbers of lights. In the five cities consuming the largest number of lights, the average cost is far above that in the five cities consuming the smallest number. That something is radically wrong must be apparent. By one not initiated in the mysteries of city contracts, the very opposite would be expected. And if the charges were governed by the cost of production, that is what the statistics would show. Every increase in the number of lights is made at a less than proportionate increase in expenditure. The capacity of the plant may be doubled without doubling the investment. This is the primary characteristic of a natural monopoly, and every business in which this state of affairs exists must necessarily be viewed as monopolistic in its nature. Whether the fact that large cities using many lights are paying more per light than small cities using few, is the result of ignorance, imposition, or corruption, the fact still remains, and the only remedy is enlightenment.

Before proceeding further, it might be well to note one more peculiarity evinced by this investigation. The efficacy of competition as a regulating influence is something almost implicitly confided in by the American people. They do not recognize the monopolistic character of certain industries. Now in many instances it was stated in the answers received from the various cities that the city was illuminated by contract with two and often three different electric lighting companies. But in no single case was any variation in the charge noted. Each company received the same price per light as the others. The only explanation which can be made is that by some combination the same price was fixed for each company, and that the latter divided the territory according to mutual agreement. The impossibility of competition in this line of business could not have been more clearly illustrated.

We may now ask, what is the condition of affairs in those cities which own their own electric lighting plants? In the report of the Scranton committee, the statistics are given as follows:—

Name of Place.	No. Lights.	Cost per Annum.	Hours Lighted.
Martinsville, Ind	30	$40 00	Midnight.
Grand Lodge	32	62 00	12 o'clock.
Huntington	50	48 64	All night.
Decatur, Ill	52	60 00	All night.
Dunkirk, N. Y	55	36 50	All night.
Paris, Ill	60	36 00	Except moonlight.
Easton, Pa	64	100 00	All dark nights.
Aurora, Ill	75	56 00	Except moonlight.
Painesville, O.	80	35 00	Except moonlight.
Ypsilanti, Mich	80	23 61	12 P. M., not moonlight.
Madison, Ind	85	48 00	All night.
Lewiston, Me	96	42 00	All night.
Hannibal, Mo	96	52 00	All night.
Little Rock	110	47 50	When dark.
Bay City, Mich	134	60 00	All night.
Topeka, Kan	184	54 00	Eight hours.
Topeka, Kan	184	72 00	All night.
Chicago	293	65 60	All night.

The difference between this table and the one above is surprisingly great. One cannot but wonder, upon comparing the two, why the great electric lighting companies are no richer. The averages under the two systems are instructive. The average price paid to private parties by the various cities is $105.13 per light each year. The same service when performed directly under municipal management averages to the citizens a cost of $52.12½. Under the former method, Boston pays annually the enormous sum of $180 per light, while the greatest cost under public control is $100 paid by Easton, Pa. The lowest amount which corporate greed will take to loose its hold upon the public purse is paid in Cortland, N. Y., to the sum of $50 per light each year. But Ypsilanti, Mich., by supplying herself with nightly illumination, has been able to keep the expense for the same work down to $23.61.

The first and only conclusion to be drawn from a study of these figures is that cities can supply their own electric lighting much more cheaply and advantageously than they can obtain it from private parties. Individual corporations cannot dispose of their product at the same price and retain a reasonable profit. The very fact that an increased number of lights are obtained at a less than proportionate increase of outlay is a strong argument in favor of municipal management. A greater number of lights are made necessary by the natural growth of a city. There is no reason why the sum thus saved, hitherto put into the coffers of private corporations, should not, by being turned into the public treasury, inure to the benefit of the people. Besides, it costs but little more to burn the lamps ten hours than for six. If the lamps burn all night no more linemen nor other employes are required.

Many cities, recognizing the advantages in owning certain enterprises, are manufacturing their own gas; many more are supplying themselves with water. In such places great saving could be effected by running an electric lighting plant in conjunction with the water works. This has been done in Dunkirk, N. Y., and has proven profitable to the city. If desirable, commercial lights might be sold and the revenue thus accruing would lessen the amount necessary to be raised by taxes. In this way the taxpayer would reap some direct benefit from the undertaking.

But it may be argued that various other considerations should be taken into account. Many municipalities stand in greater need of other improvements which demand their entire resources. To these it seems better to postpone the acquisition of an electrical plant and to leave the matter for the present in private hands. The changing condition of the electrical industry, the constant application of new inventions, the probable discovery of new processes, all advise that haste be made slowly. But that does not disprove the advisability of taking measures to obtain, without friction, municipal control of this industry in the near future. Where individuals have already invested their capital in such undertakings, it is always more difficult to bring about the change; for they will take pains to prevent it as long as possible. As long as they can control the primaries and nominating conventions, the corporations are always "out of politics." They are for either party, but above all for themselves. The corruption which might possibly result from the extension of municipal functions to electric lighting and other monopolies of service, is not to be compared with the pernicious influence upon politics of private companies when seeking fat city contracts.

There are frequent complaints under the system of private management. In Scranton, the local company persisted in furnishing a light of less power than that called for in their agreement. Investigation showed that instead of giving a 2,000 c. p. arc light, the lights had never been over 800 c. p. and very seldom that, even under the most favorable circumstances. Very often they had run down to 400 or 500 c. p. The poles were placed in arbitrary positions, and the company failed to supply the lamps at intersections. This last neglect made necessary an increased number of lights, which increase, of course, added to the profit of the company. The dirty condition of the globes furnished another cause for complaint. As far as the wires are concerned, the public is well aware of the threatening danger. Every one acknowledges that the wires ought to be placed underground; but the recent experience in New York city has shown the strength as well as the present humor of the great corporations. Such trouble would be very unlikely to arise if these industries were under public control.

The advantages of public ownership of natural monopolies are beginning to be appreciated. The owners of the electric lighting companies have perceived the trend of public opinion. One of them, in a recent work upon the subject, has enunciated the astounding principle that electric lighting, above all other industries, "is the field for private monopoly." But this proposition is far from being generally accepted. Theory as well as practice points to an opposite direction. At the banquet of the Boston Merchants' Association last winter, the Hon. Seth Low, former Mayor of Brooklyn, and recently installed President of Columbia College, said, during his speech in favor of municipal ownership of these monopolies of service, "that the result of his experience in the Mayor's office for four years had been to change the whole current of his thoughts, which formerly ran away from that conclusion." In view of the general satisfaction expressed by the citizens of those cities operating their own electric lighting plants, one can scarcely fail to agree with the opinion expressed in the report of the Scranton committee to the effect that "the day is rapidly approaching when cities will no longer submit to so barefaced a fleecing process, but will own their respective plants and thus reduce the cost of lighting to a minimum."

MAGNETISM.[1]

BY DR. JOHN HOPKINSON, F. R. S.

As old as any part of electrical science is the knowledge that a needle or bar of steel which has been touched with a loadstone will point to the north. Long before the first experiments of Galvani and Volta the general properties of steel magnets had been observed—how like poles repelled each other, and unlike attracted each other; how the parts of a broken magnet were each complete magnets with a pair of poles. The general character of the earth's magnetism has long been known—that the earth behaves with regard to magnets as though it had two magnetic poles respectively near the rotative poles, and that these poles have a slow secular motion. For many years the earth's magnetism has been the subject of careful study by the most powerful minds. Gauss organized a staff of voluntary observers, and applied his unsurpassed powers of mathematical analysis to obtaining from their results all that could be learned.

The magnetism of iron ships is of so much importance in navigation that a good deal of the time of men of great power has been devoted to its study. It was *the* scientific study of Archibald Smith; and Airy and Thomson have added not a little to our practical knowledge of the disturbance of the compass by the iron of the ship. Sir William Thomson, in addition to much valuable practical work on the compass, and experimental work on magnetism, has given the most complete and elegant mathematical theory of the subject. Of late years the development of the dynamo machine has directed attention to the magnetization of iron from a different point of view, and a very great deal has been done by many workers to ascertain the facts regarding the magnetic properties of iron. The upshot of these many years of study by practical men interested in the mariner's compass or in dynamo machines by theoretical men interested in looking into the nature of things, is that, although we know a great many facts about magnetism, and a great deal about the relation of these facts to each other, we are as ignorant as ever we were as to any reason why the earth is a magnet, as to why its magnetic poles are in slow motion in relation to its substance, or as to why iron, nickel, and cobalt are magnetic, and nothing else, so far as we know, is to any practical extent. In most branches of science the more facts we know the more fully we recognize a continuity, in virtue of which we see the same property running through all the various forms of matter. It is not so in magnetism; here the more we know the more remarkably exceptional does the property appear, the less chance does there seem to be of resolving it into anything else. It seems to me that I cannot better occupy the present occasion than by recalling your attention to, and inviting discussion of, some of those salient properties of magnetism as exhibited by iron, nickel, and cobalt—properties most of them very familiar, but properties which any theory of magnetism must reckon with and explain. We shall not touch on the great subject of the earth as a magnet—though much has been recently done, particularly by Rücker and Thorpe, but deal simply with magnetism as a property of these three bodies, and consider its natural history, and how it varies with the varying condition of the material.

To fix our ideas, let us consider, then, a ring of uniform section of any convenient area and diameter. Let us suppose this ring to be wound with copper wire, the convolutions being insulated. Over the copper wire let us suppose that a second wire is wound, also insulated, the coils of each wire being arranged as are the coils of any ordinary modern transformer. Let us suppose that the ends of the inner coil, which we will call the secondary coil, are connected to a ballistic galvanometer; and that the ends of the outer coil, called the primary, are connected, through a key for reversing the current, with a battery. If the current in the primary coil is reversed, the galvanometer needle is observed to receive a sudden or impulsive deflection, indicating that for a short time an electromotive force has been acting on the secondary coil. If the resistance of the secondary circuit is varied, the sudden deflection of the galvanometer needle varies inversely as the resistance. With constant resistance of the secondary circuit the deflection varies as the number of convolutions in the secondary circuit. If the ring upon which the coils of copper wire are wound is made of wood or glass—or, indeed, of 99 out of every 100 substances which could be proposed—we should find that for a given current in the primary coil the deflection of the galvanometer in the secondary circuit is substantially the same. The ring may be of copper, of gold, of wood, or glass—it may be solid or it may be hollow—it makes no difference in the deflection of the galvanometer. We find, further, that with the vast majority of substances the deflection of the galvanometer in the secondary circuit is proportional to the current in the primary circuit. If, however, the ring be of soft iron, we find that the conditions are enormously different. In the first place, the deflections of the galvanometer are very many times as great as if the ring were made of glass, or copper, or wood. In the second place, the deflections on the galvanometer in the secondary circuit are not proportional to the current in the primary circuit; but as the current in the primary circuit is step by step increased we find that the gal-

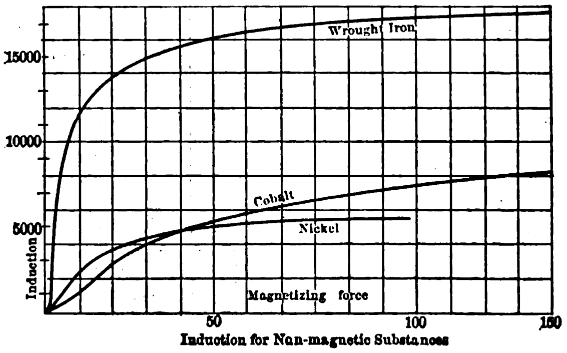

FIG. 1.

---

[1] A paper read before the Institution of Electrical Engineers, London.

vanometer deflections increase somewhat, as is illustrated in the accompanying curve, Fig. 1, in which the abscissæ are proportional to the primary current, and the ordinates are proportional to the galvanometer deflections. You observe that as the primary current is increased the galvanometer deflection increases at first at a certain rate; as the primary current attains a certain value the rate at which the deflection increases therewith is rapidly increased, as shown in the upward turn in the curve. This rate of increase is maintained for a time, but only for a time. When the primary current attains a certain value the curve bends downward, indicating that the deflections of the galvanometer are now increasing less rapidly as the primary current is increased; if the primary current be still continually increased, the galvanometer deflections increase less and less rapidly.

Now what I want to particularly impress upon you is the enormous difference which exists between soft iron on the one hand, and ordinary substances on the other. On this diagram I have taken the galvanometer deflections to the same scale for iron, and for such substances as glass or wood. You see that the deflections in the case of glass or wood, to the same scale, are so small as to be absolutely inappreciable, whilst the deflection for iron at one point of the curve is something like 2,000 times as great as for non-magnetic substances. This extraordinary property is possessed by only two other substances besides iron—cobalt and nickel. On the same figure are curves showing on the same scale what would be the deflections for cobalt and nickel, taken from Professor Rowland's paper. You observe that they show the same general characteristics as iron, but in a rather less degree. Still, it is obvious that these substances may be broadly classed with iron in contradistinction to the great mass of other bodies. On the other hand, diamagnetic bodies belong distinctly to the other class. If the deflection with a non-magnetic ring be unity, that with iron, as already stated, may be as much as 2,000; that with bismuth, the most powerful diamagnetic known, is 0.999825—a quantity differing very little from unity. Note, then, the first fact which any theory of magnetism has to explain is: Iron, nickel, and cobalt, all enormously magnetic; other substances practically non-magnetic. A second fact is: With most bodies the action of the primary current on the secondary circuit is strictly proportional to the primary current; with magnetic bodies it is by no means so.

You will observe that the ordinates in these curves, which are proportional to the kicks or elongations of the galvanometer, are called induction, and that the abscissæ are called magnetizing force. Let us see a little more precisely what we mean by the terms, and what are the units of measurement taken. The elongation of the galvanometer measures an impulsive electromotive force—an electromotive force acting for a very short time. Charge a condenser to a known potential, and discharge it through the galvanometer; the needle of the galvanometer will swing aside through a number of divisions proportional to the quantity of electricity in the condenser—that is, to the capacity and the potential. From this we may calculate the quantity of electricity required to give a unit elongation. Multiply this by the actual resistance of the secondary circuit and we have the impulsive electromotive force in volts and seconds, which will, in the particular secondary circuit, give a unit elongation. We must multiply this by 10^8 to have it in absolute C. G. S. units. Now the induction is the impulsive electromotive force in absolute C. G. S. units divided by the number of secondary coils and by the area of section of the ring in square centimeters. The line integral of magnetizing force is the current in the primary in absolute C. G. S. units—that is, one-tenth of the current in amperes—multiplied by 4π. The magnetizing force is the line integral divided by the length of the line over which that line integral is distributed. This is, in truth, not exactly the same for all points of the section of the ring—an imperfection so far as it goes in the ring method of experiment. The absolute electro-magnetic C. G. S. units have been so chosen that if the ring be perfectly non-magnetic the induction is equal to the magnetizing force. We may refer later to the permeability, as Sir William Thomson calls it; it is the ratio of the induction to the magnetizing force causing it, and is usually denoted by μ.

There is a further difference between the limited class of magnetic bodies and the great class which are non-magnetic. To show this, we may suppose our experiment with the ring to be varied in one or other of two or three different ways. To fix our ideas, let us suppose that the secondary coil is collected in one part of the ring, which, provided that the number of turns in the secondary is maintained the same, will make no difference in the result in the galvanometer. Let us suppose, further, that the ring is divided, so that its parts may be plucked from one another, and the secondary coil entirely withdrawn from the ring. If now the primary current have a certain value, and if the ring be plucked apart and the secondary coil withdrawn, we shall find that, whatever be the substance of which the ring is composed, the galvanometer deflection is one-half of what it would have been if the primary current had been reversed. I should perhaps say approximately one-half, as it is not quite strictly the case in some samples of steel, although, broadly speaking, it is one-half. This is natural enough, for the exciting cause is reduced from—let us call it a positive value, to nothing when the secondary coil is withdrawn; it is changed from a positive value to an equal and opposite negative value when the primary current is reversed. Now comes the third characteristic difference between the magnetic bodies and the non-magnetic. Suppose that, instead of plucking the ring apart when the current had a certain value, the current was raised to this value and then gradually diminished to nothing, and that then the ring was plucked apart and the secondary coil withdrawn. If the ring be non-magnetic, we find that there is no deflection of the galvanometer; but, on the other hand, if the ring be of iron, we find a very large deflection, amounting, it may be, to 80 or 90 per cent. of the deflection caused by the withdrawal of the coil when the current had its full value. Whatever be the property that the passing of the primary current has imparted to the iron, it is clear that the iron retains a large part of this property after the current has ceased. We may push the experiment a stage further. Suppose that the current in the primary is raised to a great value, and is then slowly diminished to a smaller value, and that the ring is opened and the secondary coil withdrawn. With most substances we find that the galvanometer deflection is precisely the same as if the current had been simply raised to its final value. It is not so with iron; the galvanometer deflection depends not alone upon the current at the moment of withdrawal, but on the current to which the ring has been previously subjected.

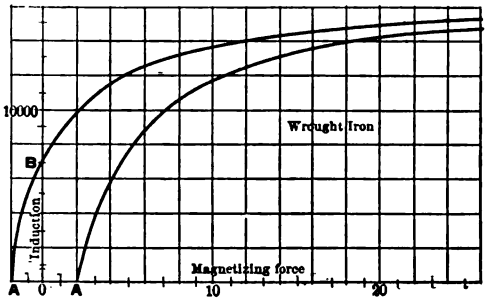

FIG. 2.

We may then draw another curve, Fig. 2, representing the galvanometer deflections produced when the current has been raised to a high value and has been subsequently reduced to a value indicated by the abscissæ. This curve may be properly called a descending curve. In the case of ordinary bodies this curve is a straight line coincident with the straight line of the ascending curve, but for iron it is a curve such as is represented in the diagram. You observe that this curve descends to nothing like zero when the current is reduced to zero; and that when the current is not only diminished to zero, but is reversed, the galvanometer deflection only becomes zero when the reversed current has a substantial value. This property possessed by magnetic bodies of retaining that which is impressed upon them by the primary current has been called by Professor Ewing "hysteresis," or, as similar properties have been observed in quite other connections, "magnetic hysteresis." The name is a good one, and has been adopted. Broadly speaking, the induction as measured by the galvanometer deflection is independent of the time during which the successive currents have acted, and depends only upon their magnitude and order of succession. Some recent experiments of Professor Ewing, however, seem to show a well-marked time effect. There are curious features in these experiments which require more elucidation.

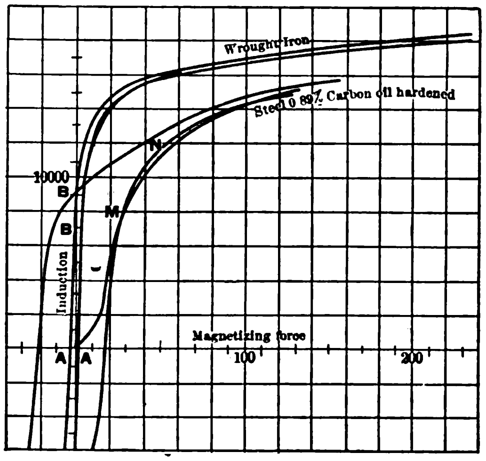

FIG. 3.

It has been pointed out by Warburg, and subsequently by Ewing, that the area of curve 2 is a measure of the quantity of energy expended in changing the magnetism of the mass of iron from that produced by the current in one direction to that produced by the current in the opposite direction and back again. The energy expended with varying amplitude of magnetizing forces has been determined for iron, and also for large magnetizing forces for a considerable variety of samples of steel. Different sorts of iron and steel differ from each other very greatly in this respect. For example, the energy lost in a complete cycle of reversals in a sample of Whitworth's mild steel was about 10,000 ergs per cubic centimeter; in oil-hardened hard steel it was near 100,000, and in tungsten steel it was near 200,000—a range of variation of 20 to 1. It is, of course, of the greatest possible importance to keep this quantity low in the case of armatures of dynamos, and in that of the cores of transformers. If the armature of a dynamo machine be made of good iron, the loss from hysteresis may easily be less than one per cent.; if, however, to take an extreme case, it were made of tungsten steel, it would readily amount to 20 per cent. In the case of transformers and alternate current dynamo machines, where the number of reversals per second is great, the loss of power by hysteresis of the iron, and the consequent heating, become very important. The loss of power by hysteresis increases more rapidly than does the induction. Hence it is not well in such machines to work the iron to anything like the same intensity of induction as is desirable in ordinary continuous current machines. The quantity O A when measured in proper units, as already explained—that is to say, the reversed magnetic force, which just suffices to reduce the induction as measured by the kick on the galvanometer to nothing after the material has been submitted to a very great magnetising force—is called the "coercive force," giving a definite meaning to a term which has long been used in a somewhat indefinite sense. The quantity is really the important one in judging the magnetism of short permanent magnets. The residual magnetism, O B, is then practically of no interest at all; the magnetic moment depends almost entirely upon the coercive force. The range of magnitude is somewhat greater than in the case of the energy dissipated in a complete reversal. For very soft iron the coercive force is 1.6 C. G. S. units; for tungsten steel, the most suitable material for magnets, it is 51 in the same units. A very good guess may be made of the amount of coercive force in a sample of iron or steel by the form of the ascending curve, determined as I described at first. This is readily seen by inspection of Fig. 3, which shows the curves in the cases of wrought iron, and steel containing 0.9 per cent. of carbon. With the wrought iron a rapid ascent of the ascending curve is made, when the magnetizing force is small and the coercive force is small; in the case of the hard steel the ascent of the curve is made with a larger magnetizing current, and the coercive force is large. There is one curious feature shown in the curve for hard steel which may, so far as I know, be observed in all magnetizable substances; the ascending curve twice cuts the descending curve, as at M and N. This peculiarity was, so far as I know, first observed by Professor G. Wiedemann.

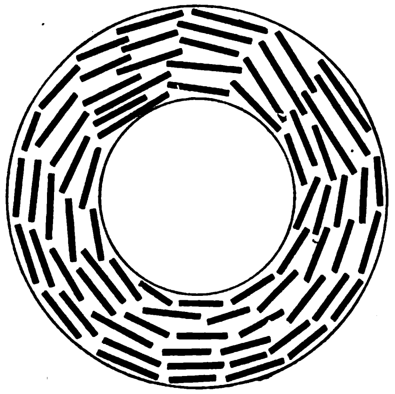

FIG. 4.

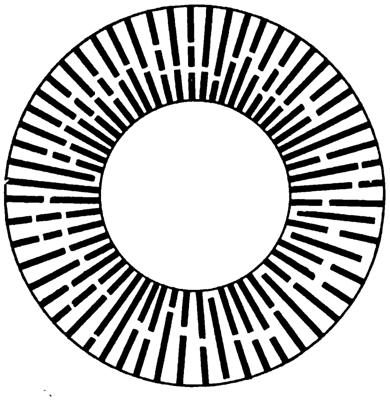

FIG 5.

I have already called emphatic attention to the fact that magnetic substances are enormously magnetic, and that non-magnetic substances are hardly at all magnetic; there is between the two classes no intermediate class. The magnetic property of iron is exceedingly easily destroyed. If iron be alloyed with 12 per cent. of manganese, the kick on the galvanometer which the material will give, if made into a ring, is only about 25 per cent. greater than is the case with the most completely non-magnetic material instead of being some hundreds of times as great, as would be the case with iron. Further, with this manganese steel, the kick on the galvanometer is strictly proportional to the magnetizing current in the primary, and the material shows no sign of hysteresis. In short, all its properties would be fully accounted for if we supposed that manganese steel consisted of a perfectly non-magnetic material, with a small percentage of metallic iron mechanically admixed therewith. Thus the property of non-magnetizability of manganese steel is an excellent proof of the fact—which is also shown by the non-magnetic properties of most compounds of iron—that the property appertains to the molecule, and not to the atom; or, to put it in another way, suppose that we were to imagine manganese steel broken up into small particles; as these particles became smaller there would at length arrive a point at which the iron and the manganese would be entirely separated from each other; when this point is reached the particles of iron are non-magnetic. By the magnetic molecule of the substance we mean the smallest part which has all the magnetic properties of the mass. The magnetic molecule must be big enough to contain its proportion of manganese. In iron, then, we must have a collection of particles of such magnitude that it would be possible for the manganese to enter into each of them, to constitute an element of the magnet. Manganese is, so far as I know, a non magnetic element. Smaller proportions of manganese reduce the magnetic property in a somewhat less degree, the reduction being greater as the quantity of manganese is greater. It appeared very possible that the non-magnetic property of manganese steel was due to the coercive force being very great—that in fact, in all experiments we were still on that part of the magnetization curve below the rapid rise, and that if the steel were submitted to greater forces it would presently prove to be magnetic, like other kinds of steel. Professor Ewing, however, has submitted manganese steel to very great forces indeed, and finds that its magnetism is always proportional to the magnetizing force.

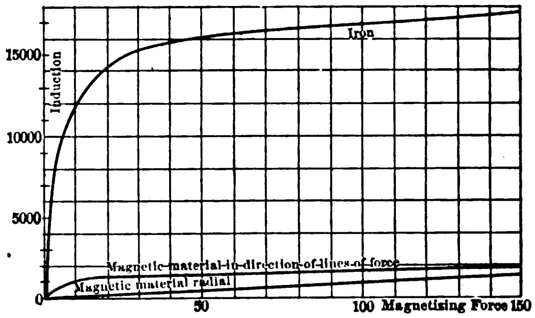

FIG. 6.

No single body is known having the property of capacity for magnetism in a degree which is neither very great nor very small, but intermediate between the two extremes. We can, however, mix magnetic and non-magnetic substances to form bodies apparently intermediate. It is, therefore, interesting to consider what the properties might be of such a mixture. It depends quite as much on the way in which the magnetic part is arranged in the mass, as on its actual quantity. Suppose, for example, it is arranged as in Fig. 4—in threads or plates having a very long axis in the direction of the magnetizing force—we may at once determine the curve of magnetization of the mixture from that of the magnetic substance by dividing the induction for any given force in the ratio of the whole volume to the volume of magnetic substance. If, on the other hand, it is as in Fig. 5—with a very short axis in the direction of the force, and a long axis perpendicular thereto—we can equally construct the curve of magnetization. This is done in Fig. 6, which shows the curve when nine-tenths of the material is highly magnetic iron arranged as in Fig. 5, whilst the other curve of the same figure is that when only one-tenth is magnetic, but arranged as in Fig. 4. You observe how very different is the character of the curve—a difference which is reduced by the much less proportion of magnetic material in the mixture in the one case than in the other. One peculiarity of these arrangements of the two materials in relation to each other is that the resulting material is not isotropic—that is, its properties are not the same in all directions, but depend upon the direction of the magnetizing force in the material. Of course, this is not at all a probable arrangement, but it is instructive in showing the character of the result as depending upon the construction of the material. Let us, however, consider the simplest isotropic arrangement; let us suppose that one material is in the form of spheres bedded in a matrix of the other: if the spheres are placed at random this is clearly an isotropic arrangement. The result is very different according as the matrix or the spheres are of the magnetic material. Suppose that the volume of the spheres is one-half of the whole volume. In Fig. 7, we have approximately the curve for iron, for a mixture of equal quantities of iron and a non-magnetic material, the spheres being non-magnetic and the matrix iron; and for a mixture, the spheres being iron, and the matrix non-magnetic. Observe the great difference. When the spheres are iron the induction is near four times the force for all values of the force. When the matrix is iron the induction is near two-fifths of the induction when the material is iron only.

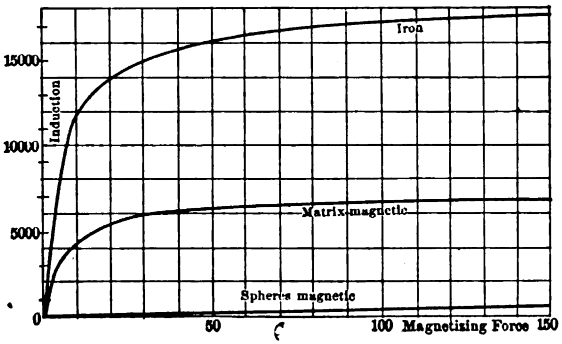

FIG. 7.

(To be continued.)

CORRESPONDENCE.

NEW YORK AND VICINITY.

A Dinner to Col. Gouraud.—A Proposed State Electrical Board.—The Lockport Water Co.'s Electrical Power Scheme.—Trying to Regulate Telephone Rates.—A Meeting of the Subway Board.

AN interesting dinner was given last Thursday by Col. Gouraud to some of his friends of the Grand Army of the Republic, chiefly old comrades in the Third Cavalry, in which he started as a private and ended as a captain, being breveted a colonel for valor in the field. The menu was a very tasteful production, and it is needless to say that the dinner, which was served in the Moorish room at the Hoffman House, was all that could be asked. A large number of electrical people were present. including Genl. E. S. Greeley, Commodore Cheever, E. N. Dickerson, S. S. Moriarty, S. Insull, Mr. Gottschalk, Dr. Archibald, of London, Mr. Evans, of the North American Phonograph Co., and Jesse Seligman, the banker, and other notables. The room was handsomely decorated with English and American flags, and portraits of Sherman and Gladstone adorned the walls. General Greeley made a glowing speech appropriate to the occasion, and other oratory was also enjoyed. There was an extremely good exhibition of the phonograph, including the English bugle calls, and a wonderful imitation, by means of the kettledrum played into it, of Union soldiers on a train passing through a body of Confederate troops, and exchanging volleys with them. The evening passed away most happily. Mr. Edison had been invited but unfortunately could not be present, though he was not forgotten. Col. Gouraud sails for England in a few days.

Mr. Nolan has introduced a bill in the state legislature creating a board of three commissioners to be the State Board of Electrical Control, to be appointed by the governor and confirmed by the senate. One shall hold office for three, one for four, and one five years. One shall be chosen from the party casting the largest number of votes for governor at the last election, and one shall be an electrical expert. After the expiration of the first term, the terms shall be five years. The board shall have a secretary, to be appointed by the governor and confirmed by the senate to serve for five years. If the expert commissioner is from one political party, the secretary must be from another. The secretary shall be the executive officer of the board, and shall receive $4,000 yearly. The annual salary of each commissioner shall be $8,000. The board may appoint an inspector at $3,000 a year. In many respects the bill conforms to Mr. Roesch's Electrical Commission Bill.

The bill allowing the Lockport Water Co. to supply electricity and to take power from the Niagara river was reported last week in the legislature, amended so that the operations of the company are confined to Niagara, Orleans and Erie counties. The company is also to be subject to the general laws of the state and the municipal laws of the cities where it supplies electricity. Mr. Connelly moved to disagree with the report because it was the same as that which the assembly defeated. Mr. Husted said the bill was not killed; it was simply recommitted, and the committee had reported instead the Senate bill. Mr. Andrus suggested that the bill first be printed, and Mr. Connelly agreed.

The members of the Legislature are not quite of one mind as to what people should pay for telephone service, and consequently two bills on the subject have been introduced. One by Mr. Sullivan fixes the charge for telephones in cities of 500,000 inhabitants and over, at not more than $5 per month; in cities of between 100,000 and 500,000 at not more shan $3.75 per month; and in cities of less than 100,000 at $2.75 per month. Mr. Kerrigan came to the front with a bill calculated to worry the telephone people. It provides that in cities having a population of 500,000 and over, the charge for telephones shall not exceed $6 per month; in cities having 100,000 and less than 500,000 population, not more than $3.75 per month, and in cities having less than 100,000 population, a sum not exceeding $2.75 per month. The Assembly Committee on Electricity heard argument last week by Simon Sterne, representing the Telephone Subscribers' Association of New York, on the Clark Telephone Charges Regulation bill. He urged that $80 a year for telephones would give a fair profit to the companies.

The Board of Electrical Control held an important meeting in the mayor's office last week. The decision of the general term of the Supreme Court on the contract with the Standard Subway Co. was brough up, but action was postponed because the order of the Supreme Court had not been settled. Commissioner Gilroy told the board that he had had a conference with the representatives of the electric lighting companies, and he found that every street that he had decided to pave was to have subways laid in it. He said that he would not agree to permit the laying of subways in any street after it was repaved. W. H. Peckham wanted the whole matter postponed. Edward Lauterbach was anxious to have the work on the Edison system done at once, but every other company objected. It was finally decided to put the matter over until Thursday, April 3, and Mayor Grant said that the work on such streets as are to be paved would be ordered on that day. Ex-Commissioner Gibbens made an application on behalf of the Empire and Bay State Telegraph Co. to erect 10 wires on its own line of poles from Yonkers to the Harlem river, where connection will be made with the Western Union Telegraph Co. The application was granted.

Mr. Emil Rathenau, the general director of the Allgemeine Elektricitæts Gesellschaft, or Edison company, of Berlin, is on a visit to this country, quietly making notes and observations on what he sees in progress.

NEW YORK, April 7, 1890.

BOSTON.

The New Telephone Building.—Meeting of the New England Electric Exchange.—Next Dinner of the Boston Electric Club.—Paper by Mr. Wetzler, and Prospective Ladies' Night.—West End Electric Cars and Rapid Transit.—Meeting of the Boston Society of Civil Engineers.—The Massachusetts Legislature and Electric Legislation.

THE new telephone building on Ninth street is rapily appoaching completion, and arrangements can now be made for offices.

The New England Electric Exchange held an examination this week at the rooms of the Boston Electric Club, at which there were about twenty-five applicants examined for competency.

The next dinner of the Boston Electric Club will be held at the Quincy House, on Monday evening, April 14, when Mr. Joseph Wetzler, editor of THE ELECTRICAL ENGINEER, will read a paper on "Electric Railway Evolution." The lecture will be profusely illustrated with stereopticon views. The house and entertainment committee have also arranged for a ladies' evening on Wednesday the 23d inst., and special arrangements are being made to have a few electrical novelties to interest the ladies, among them being the electric piano, the phonograph, and an Edison toy speaking doll.

The subject of rapid transit is still agitating the people of Boston, especially the residents of the suburbs. The electric car is now no novelty in Boston, and up to within a week ago was rapidly becoming the favorite means of travel. A considerable distance can really be covered in an amazingly short space of time, and with the exception of a few chronic "kickers," they meet the approbation of the public. One or two accidents lately, one unfortunately resulting fatally, have given these "kickers" an opportunity to arouse public feeling, and lately an order was passed by the Board of Aldermen restricting the speed of the electric cars to seven miles an hour in the city proper and twelve miles an hour outside. The West End Street Railway Co., however, for reasons best known to themselves, appear to have reduced even that speed in the city to about five or six miles an hour, and now the electric cars are actually a hindrance to the old rapid transit by horse cars. Even the most emphatic kickers now ride in the cars with a weary expression on their face, and will actually walk a block or two to get to a line which is operated by the old reliable horse power. Something will have to be done very soon, whether in the shape of more rapid surface travel or in an elevated railroad franchise, remains to be seen. The new Thomson-Houston electric locomotive, designed to be used in Boston, has been completed, and was successfully tried in Lynn this week. The locomotive weighs in all seven tons, and has four driving wheels each 36 inches in diameter. There are two 20 h. p. motors attached, and in addition to the ordinary wheel brake, the car is fitted with a small one h. p. motor for operating the air brake. The locomotive is capable of attaining a speed of twenty miles an hour.

Rapid transit was also made the subject of an interesting discussion by the members of the Boston Society of Civil Engineers at their monthly meeting, held this week at the American House. In the absence of the president, Vice-President John R. Freeman presided, Mr. S. C. Tinkham acting as secretary. Previous to the general discussing of the subject, Mr. James K. Tilden read an interesting paper upon "Rapid Transit in London and Boston." Mr. Tilden described in detail the workings of the London underground system, and other gentlemen then discussed the rapid transit system as applied to Paris and Berlin.

The legislature is still engaged in the hearing of remonstrants to elevated railways for the city of Boston. Mr. Ball argued against elevated railways in general, declaring that the Supreme Court would pronounce it unconstitutional to take away the rights of the streets of Boston for a new servitude, without compensation, and he prophesied that the court would be appealed to if any of these charters are granted. The committee on mercantile affairs had under consideration the order in regard to amending ch. 382 acts 1887, so that cities of more than 100,000 people may be exempt from the chapter so far as it restricts to one company the business of making and selling electric light. There was also under consideration an order of representative Clark, of Braintree, to strike from sect. 3, same chapter, the provision that "companies organized for the purpose" of going into the electric light business shall be included under the law. Messrs. E. W. Burdett, of Boston, Clark, of Braintree, and Wyman, of Hyde Park, favored a change in the law so as to permit the granting of special privileges.

BOSTON, April 5, 1890.

CHICAGO.

A New Deposition Dynamo.—A Patent Appeals Court.—The Chicago Electric Club.—The Board of Trade and the Telegraph Companies.

FOREE BAIN is just completing a very large dynamo for electrodeposition work. This machine has a capacity of 3,000 amperes delivered at a potential of from four to six volts, such as is suitable for work of this class. The armature conductors, built up of a number of wires in parallel are equivalent in cross section to a rod of 1½ square inches. He is also very busy on a new type of motor which he has just brought out and which combines many novel and interesting features.

Mr. Brown, late chief examiner of the Patent Office in electricity, and a member of the firm of Butterworth, Hall, Brown and Smith, Honoré Building, Chicago, reports that Mr. Butterworth, late Commissioner of Patents, is now working for a Patent Appeal Court to be an appeal from the commissioner and all the circuit and district courts in the United States in patent causes. The jurisdiction of the Supreme Court of the District of Columbia will be repealed by this bill. The salaries of the judges, five in number, are to be $7,500 per year. There will also be a clerk, marshal and reporter as officers of the court. The intention is to make a high-class tribunal which will crystallize and render uniform the decisions in patent matters.

The next regular meeting of the Chicago Electric Club will be held Monday evening, April 7, at the rooms of the club. Mr. J. K. Pumpelly will read a paper entitled, "Storage Batteries to the Rescue." The title is highly suggestive.

The Board of Trade has made one more effort to suppress the bucket shops by abolishing its quotation department. A three-cornered fight has grown out of the war of the Board of Trade on the bucket shops. The telegraph companies have now been drawn into the affair. They struck their first open blow by announcing that hereafter the Board of Trade business will no longer have a special exchange rate to New York, St. Louis, and other cities. This means 15 cents added to every message to and from the board. Heretofore the members on 'Change have had a 25-cent rate to New York and a 20-cent rate to St. Louis, Milwaukee, and other western exchanges. The public at the same time paid 40 cents to New York and 25 cents to the other cities. Now all will pay alike. By the Board of Trade officials this move is regarded as an unfriendly blow. President Baker hints at the organization of a new commercial telegraph company and says that it is a poor time for any company to go before the public as a friend of bucket shops and an enemy of the Board of Trade. At the general office of the Postal company the officials were prompt to say there was nothing of the nature of retaliation against the board in abolishing the special rate. The exchange rate, they said, was made to apply to business done on the floor where the expense of handling dispatches was light. They have no instruments on the floor now, and the rate naturally dies with their removal.

CHICAGO, April 5, 1890.

ST. LOUIS.

City Lighting.—Tests of Arc Lamps.—Electric Railway Development.—An Action for Fraud against a Telegraph Instructor.

THE bill authorizing an extension of time to the Municipal Electric Light and Power Co., which has been hanging over in the House of Delegates for some time, was taken up and amended to read 120 days from January 1, 1890, and was then passed. On the following evening the amended bill reached the council and was promptly passed. The effect of this bill is to remit the fine of $500 per day and to postpone the date for beginning the city lighting until May 1.

The photometric measurements of the Wood and Jenney arc lights of the Municipal Electric Light and Power Co., which were carried out last week by the Supervisor of City Lighting, under the direction of the Board of Public Improvements, has resulted in favor of the Wood lamp. The mammoth plant of this company is now nearing completion, and as all obstacles have been removed, they confidently expect to turn on their 1,800 arc lights on April 15.

Eight electric railroad bills passed the Municipal Assembly just before its annual adjournment. The Lindell Railway Co., and Benton-Bellfountain Co., are authorized to erect overhead wires in the down-town district. This enables them to equip the entire length of their lines with electric power. The Missouri Railroad Co. is authorized to change to electric power throughout its entire length, including a new extension to Forest Park. The Forest Park, Laclede and Fourth Street Railroad Co., which is a branch line of the Missouri Railroad Co., is authorized to change to electric power. The Mound City Street Railway Co. is authorized to change to electric power throughout its entire length.

The Union Depot Railroad is authorized to make extensions on Jefferson avenue and Arsenal street, and to operate these extensions and the main lines connected therewith by electric power. The St. Louis Central and Western Railway Co., a new oganization intended eventually to take over the old Cable and Western Railroad, is authorized to build an extension to Forest Park and to equip with electric power from Twenty-second street westward. Two of the above roads—the Missouri and the Cable and Western have cable divisions in operation, but the success of electric railroads during the past year has brought about a change of heart in the management and they will give electric power a trial.

The St. Louis Railroad Co. is authorized to change its motive power to cable or electric and to lay two additional tracks. On the Seventh street line, the Short double trolley parallel system will be tried. Preparations were being made to cable the main or Broadway line, but since all the other roads have been granted privileges for overhead wires through the down-town district they are about to reconsider electric power for the main line. The liberal action of the Municipal Assembly toward the street car companies indicates that they are wide awake to the advantages of electric street cars and also to the prosperity of the city.

Henry C. Roeth, proprietor of the Union Telegraph Instruction Co., is held for the Grand Jury in the sum of $1,000 for fraud. His mode of procedure was to advertise for young men and women to learn telegraphy and take positions when qualified at salaries from $75 to $175 per month. It is needless to say no one ever qualified for any such position. His case was investigated by the State Labor Commissioner with the above result.

The Westinghouse people have placed two of their new alternating current arc lamps on exhibtion at the power house of the Missouri Electric Light and Power Co. One lamp is also placed on exhibition at the testing grounds of the Municipal Co., corner of Delmar avenue and Sarah street, during the photometric tests of of the Wood and Jenney arc lights.

ST. LOUIS, April 2, 1890.

PITTSBURGH.

A National Labor Union of Electricians.—Electric Railway work.—Street Railway Litigation.

A MOVEMENT is on foot among the employees of the various electric light companies of this city for the formation of a national union of electricians. The causes that brought about this are said to be dissatisfaction of the men with the American Federation of Labor, to which the electricians formerly belonged. A large number of the men met on Sunday, March 23, to perfect the plans for a national organization. An effort will be made to get the co-operation of all organized electrical workers in other cities and to organize unions in all cities and towns, where there are a sufficient number employed. The leaders in the movement claim that the introduction of telephones and electric lights in cities and towns is going on at such a pace that it is not chimerical to predict that there will not be less than 500,000 electrical workers in the United States in 1900. They expect that the census of this year will show 80,000 or more men, who are engaged directly or indirectly in the electric industries. As an argument in favor of this movement it was stated by one of the men interested, that they are often placed in positions where it would be impossible for an outsider to act as arbitrator, and for that reason it is essential that in the event of any difficulty between employees and the companies they should have men among their own number, who might act as judges in the case. The organization will be open to all men employed around and in connection with electric light stations, and the object will be to advance and improve the condition of the members of the organization. There are about 200 men employed as electric workmen in this city and all of them will join the organization. Another meeting will be held within a few days when the arrangements of the organization will be completed and the officers are to be elected.

A syndicate has been organized in this city with the object of buying up all the old-fashioned street car lines throughout the country and then equip them with the electric motor system. The syndicate is composed of Pittsburgh, Philadelphia and Boston capitalists with a capital of $20,000,000 at their disposal. Mr. H. Sellers McKee, the well known Pittsburgh millionaire and Mr. E. H. Clarke, of Drexel, Morgan & Co., Philadelphia, are at the head of the affair.

A corporation, known as the Homestead & Pittsburgh Connecting Railway, has been chartered in Harrisburg a few days ago with a capital stock of $300,000. This is the latest organization in this city incorporated for the purpose of building an electric road. The new line is to be a feeder of the Pittsburgh Traction Road, and it will run from Oakland, this city, to Homestead, a distance of overthree miles Operations on the road are to be commenced immediately.

Three bills in equity were filed in the Pittsburgh court on Saturday, March 28, against the Duquesne Traction Company. This is the corporation which succeeded a few weeks ago in having eleven ordinances passed in its favor in councils, mention of such fact was made in this correspondance at the time. The plaintiff is the Pittsburgh Traction Co., which claims that the Duquesne Traction Co·, is about to construct car lines on streets and avenues, for which the plaintiff already holds the franchises.

PITTSBURGH, April 4, 1890.

LETTERS TO THE EDITOR.

Notice to Correspondents.

We do not hold ourselves responsible for the opinions of our correspondents.
Anonymous communications cannot be noticed.
The Editor respectfully requests that all communications may be drawn up as briefly and as much to the point as possible.
In order to facilitate reference, correspondents, when referring to any letter previously inserted will oblige by mentioning the serial number of such letter, and of the page on which it appears.
Sketches and drawings for illustrations should be on separate pieces of paper.
All communications should be addressed EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

THE LOSSES DUE TO HYSTERESIS IN TRANSFORMERS.

[121.]—In your issue of April 2, in referring to certain remarks made by me at the recent meeting of the American Institute of Electrical Engineers on the subject of hysteresis you make the statement: "It is this constancy of relation that, as Mr. Tesla pointed out * * * may ultimately establish the correctness of the hypothesis advanced, that in reality there is no loss due to hysteresis, and that the changes of magnetization represent a charging and discharging of molecular energy without entailing an actual expenditure of energy."

I do not recollect having made such a statement, and as I was evidently misunderstood, you will greatly oblige me by inserting the following few lines, which express the idea I meant to advance:

Up to the present no satisfactory explanation of the causes of hysteresis has been given. In the most exhaustive and competent treatise on the theory of transformers, by Fleming, static hysteresis is explained by supposing that "the magnetic molecules or molecular magnets, the arrangement of which constitutes magnetization, move stiffly, and the dissipation of energy is the work done in making the necessary magnetic displacement against a sort of magnetic friction." Commonly it is stated that this is a distinct element in the loss of energy in an iron core undergoing magnetic changes entirely independent of any currents generated therein.

Now it is difficult to reconcile these views with our present notions on the constitution of matter generally. The molecules of iron cannot be connected together by anything but elastic forces, since they are separated by an intervening elastic medium through which the forces act; and this being the case is it not reasonable to assume that if a given amount of energy is taken up to bring the molecules out of their original position an equivalent amount of energy should be restored by the molecules reassuming their original positions, as we know is the case in all molecular displacements? We cannot imagine that an appreciable amount of energy should be wasted by the elastically connected molecules swinging back and forth from their original positions, which they must constantly tend to assume, at least within the limit of elasticity, which in all probability is rarely surpassed. The losses cannot be attributed to mere displacement, as this would necessitate the supposition that the molecules are connected rigidly, which is quite unthinkable.

A current cannot act upon the particles unless it acts upon currents in the same, either previously existing or set up by it, and since the particles are held together by elastic forces the losses must be ascribed wholly to the current generated. The remarkable discovery of Ewing that the magnetization is greater on the descent than on the ascent for the same values of the magnetizing force strongly points to the fact that hysteresis is intimately connected with the generation of currents either in the molecules individually or in groups of them through the space intervening. The fact observed accords perfectly with our experience on current induction, for we know that on the descent any current set up must be of the same direction with the inducing current, and, therefore, must join with the same in producing a common effect; whereas, on the ascent the contrary is the case.

Dr. Duncan stated that the ratio of increase of primary and secondary current is constant. This statement is, perhaps, not sufficiently expressive, for not only is the ratio constant but, obviously, the differential effect of primary and secondary is constant. Now any current generated—molecular or Foucault currents in the mass—must be in amount proportionate to the difference of the inductive effect of the primary and secondary, since both currents add algebraically—the ratio of windings duly considered,—and as this difference is constant the loss, if wholly accounted for in this manner, must also be constant. Obviously I mean here the transformers under consideration, that is, those with a closed magnetic circuit, and I venture to say that the above will be more pronounced when the primary and secondary are wound one on top of the other than when they are wound side by side; and generally it will be the more pronounced the closer their inductive relation.

Dr. Duncan's figures also show that the loss is proportionate to the square of the electromotive force. Again this ought to be so, for an increased electromotive force causes a proportionately increased current which, in accordance with the above statements, must entail a loss in the proportion of the square.

Certainly, to account for all the phenomena of hysteresis, effects of mechanical vibration, the behavior of steel and nickel alloy, etc., a number of suppositions must be made; but can it not be assumed that, for instance, in the case of steel and nickel alloys the dissipation of energy is modified by the modified resistance; and to explain the apparent inconsistency of this view we only need to remember that the resistance of a body as a whole is not a measure of the degree of conductivity of the particles of which it is composed.

N. TESLA.

New York City.

.... THOSE who give of their substance to aid in the promotion of science are entitled to hardly less honor than those who devote life and health and strength to the good work.—*Professor Robert H. Thurston.*

.... WE may expect that measurement classes, boldly so called, will readily find endowments; and as an incidental advantage, they may help to extinguish the popular fallacy of college workshops.—*Fleeming Jenkin.*

THE great names in connection with our progress in knowledge as to the real nature of electricity, irrespective of a mere study and extension of its known facts, are Franklin, Cavendish, Faraday and Maxwell.—*Oliver J. Lodge.*

.... WHAT is needed is a continuation of the effort already commenced, of vigorous protest against the tariff laws on the subject [scientific publications and philosophical instruments] as at present existing; laws which obstruct knowledge at its fountain head; which impose onerous burdens on a class which works gratuitously for the public good, and which place our country in a false position among the enlightened nations of the earth.—*Professor Edward D. Cope.*

SOCIETY AND CLUB NEWS.

AMERICAN INSTITUTE OF ELECTICAL ENGINEERS.

The monthly meeting of the American Institute of Electrical Engineers for April was held on the 2d inst. at Columbia College, where Professor Elihu Thomson delivered a lecture on "Some Phenomena of Alternate Current Induction," of which we present an abstract, with some running sketches representing the experiments shown. The lecture was heard and the numerous experiments were witnessed by about 300 members and their friends, and not a few ladies were present. The meeting was presided over by Seth Low, who made a charming speech of welcome, and who at the close expressed the hope that the college would soon have the opportunity of entertaining the Electrical Engineers again.

CHICAGO ELECTRIC CLUB.

On Monday, April 7, Mr. Pumpelly read a paper entitled, "Storage Batteries to the Rescue," before the Chicago Electric Club. The author showed how the accumulator made the consumer of light or power independent of the steam engine to a considerable extent, and how it may be employed to reduce the expenses of operation in many cases. Mr. Pumpelly admitted that there had been troubles in the past with storage batteries, but claimed that their durability was now sufficient to entitle them to recognition as a valuable adjunct to the steam engine and dynamo.

LITERATURE.

Traité Elementaire de l'Energie Electrique. By E. Hospitalier. Vol. I. Paris: *G. Masson,* 1890. 608 pp.

For several years the tendency of physical science has been towards a definite and properly significant terminology. This has involved, especially in the department of heat, the disuse of many time-honored terms. The development of the subject of electricity is so modern that it has not suffered so conspicuously from a mixed and inappropriate set of terms; but even here there is need of some reform. Authors of text-books and reference books have not usually shown sufficient care in promoting the reform, and have besides admitted the simultaneous use of two systems of units. M. Hospitalier has made it fundamental in his work to use a single word for each phenomenon, and to employ as units only those of the C. G. S. system. To be sure he slips occasionally, and speaks of the "*courant de rupture*" or "*extra courant*" and of "courants alternatifs" and again of "courants periodiques," meaning thereby the same thing. But the exceptions serve only to give prominence to his general usage, and his adherence to the C. G. S. system is absolute.

The book may be regarded as a sort of connecting link, on the one hand, between the more elementary books and the elaborate treatises of Maxwell and Mascart and Joubert, and, on the other, between the purely theoretical works of these men and the purely practical of some of the writers for the "Chemisch-technisch Bibliothek." There are many students of electrical engineering in the United States who will find the book as useful as it will be to the students of "L'Ecole de Physique et de Chimie Industrielles de la Ville de Paris."

M. Hospitalier avails himself of the most recent discoveries and views in regard to physical science in general and electricity in particular. The doctrines of the conservation of matter and the conservation of energy are fundamental in his treatment of his subject, and, in fact, influenced the choice of a title for his work. The treatise begins with an explanation of physical quantities and the units based on the C. G. S. system. Had the author tabulated the conclusions of this chapter he would have made it complete. The derived units, given in chapter III., would also be more useful, if for reference, if put into tabular form.

Some explanation of magnetic phenomena is fundamental to the discussion of electric phenomena, and this explanation is cleverly given in the first chapter. None of the discarded theories of magnetism are even mentioned, but the whole subject is logically developed on the basis of "lines of force" and "magnetic field." This simplicity of treatment is characteristic of the whole book which confines itself to explanation consonant with the laws of nature as understood to-day. Why authors of treatises on physics have thought it necessary to give all, or any of, the theories that have been held and abandoned, is hard to comprehend. Surely the method of giving those theories that accord with established principles is more consistent and logical, and is less confusing to the student. In this respect the work before us is successful. The reader is ready for the theory of the nature of electricity when it is briefly expounded, where it belongs, in the concluding chapter.

With the second chapter the author begins the discussion of electricity proper, and from this point on the mathematical theory is developed. Static electricity, dynamic electricity, resistances, various methods of measuring intensity, potential, quantity and capacity are treated with more or less completeness. Electro-chemistry, "*electro-thermie,*" the relations of magnetism and electricity, induction and alternating currents receive due attention. In short the way is thoroughly prepared for the discussion of applications promised in the second volume. The author adheres to the contact theory of the source of electricity, and explains it with remarkable conciseness. Indeed, whether because the French language or the author's style is especially perspicuous, there seems to be scarcely a superfluous word in the explanatory portion of the work. The same conciseness and clearness marks the mathematical discussions. The fundamental demonstrations are unusually well stated. The reader is expected to have some familiarity with the subject, but the evident aim of the author to teach as well as demonstrate is attained. In treating of static electricity the subject in which the author's methods are, perhaps, seen at their best is the theory of condensers.

The introduction to current electricity is easy and natural. The abandonment of what may be called the mixed historical and theoretical method has no better exhibition of its advantages than just here. We are spared the sight of Galvani's struggling frog and are conducted not by the path of the early experimenters but directly to the modern battery. Three short paragraphs serve to introduce us to Ohm's law. And here again the wise method of the author is shown in making the demonstration of that law indirect, the accuracy of the results obtained from measurements based on the law, being taken as proof of its truth.

The early establishment of the identity of the galvanic and magnetic field is useful as well as logical, and makes proper the immediate discussion of the tangent galvanometer. In view of the importance of that instrument it would seem that a little more complete discussion of it would have been appropriate.

The definition of resistance, given without any attempt to describe its effect on the current, is so characteristic of the author as to deserve especial mention. Ohm's law furnishes him with the definition of resistance complete and unassailable, "Le quotient de la difference de potential entre ses extremités par l'intensité du courant qui le traverse." The graphic method of representing variation of resistance with temperatures is adopted. The methods of measuring resistance, are the well-known methods already in vogue. Among the instruments measuring intensity described in the chapter on "*Galvanometrie*" is found the new (1888) universal aperiodique galvanometer of d'Arsonval and Wiedemann. The others are for the most part well known. The 'constant' of a galvanometer is so ill defined ordinarily that M. Hospitalier does a service in giving the three different meanings applied to the word, and adding the significant remark: "To avoid any confusion care should be taken never to use the word 'constant' without accurately defining it in each case."

The chapters on electrometry, generators of electric energy, and the measurement of quantity and capacity, contain descriptions and discussions of several methods of measurement, worthy of a more extended notice than we can give them. The development of expressions for the intensity, pressure and force of alternating currents is a feature of chapter VII. These play an important part in the discussions in the chapter on alternating currents.

The chapter on electro-chemistry, is devoted to the theory of primary batteries (called by the author "piles hydro-electriques"), polarization, electrolysis and secondary batteries. It is unfortunate that M. Hospitalier should give the weight of his name to the word "Accumulators" instead of "Secondary Batteries." The idea of storing up electricity as if it were some form of matter, is so foreign to modern ideas, that there is little reason for the use of a word that implies accumulation, and such phraseology is not in harmony with the rest of the work. The selection of primary batteries for description is judicious. It is a relief, after the bewildering variety that finds place in many books, to find an author who confines himself to the few that are essential. The description of M. Moissau's isolation of fluorine is an interesting addition to the subject of electrolysis, and its introduction is justified by reason of the difficulties that beset the experiment. Under the head of "Electro-thermie," the author includes both the thermal effects of the current and thermo-electricity. Some very recent applications of the thermal effects in instruments of measurement are described here. These are Ayrton and Perry's thermic voltmeter (1887) and Mr. F. J. Smith's ingenious, if not immediately practical, apparatus in which the heat of the current causes water to expand and indicate the amount of current by the amount of expansion.

The subjects treated in the remainder of the book have been greatly developed in the past few years, and the author has shown unusual enterprise in incorporating into his work abstracts of recent articles and new inventions. The electro-dynamic balance of Sir W. Thomson and the ampere standard of M. Pellat, serve to illustrate the application of electro-dynamic laws, and recent contributions on the subject of induction are used to aid in determining co-efficients and constants. The difference in phase between the two alternating currents, primary and secondary, in a transformer is traced to a sluggishness in the magnetization of the iron core. This seems a little strange in view of the experiments of Professor S. P. Thompson and Mr. W. M. Mordey on the alleged magnetic lag in dynamos, and one is inclined to look farther for the explanation of what is undoubtedly a fact. The otherwise excellent chapter on alternating currents is marred by the only imperfect cuts in the book.

This book should have many readers in this country. The number pursuing courses of study in electricity will find it an excellent introduction to Maxwell. It is not intended for beginners, and such should not attempt it; but the more advanced student and the electrical engineer will find it interesting and instructive. He will be pleased with the typography and general make-up of the book, and will follow with pleasure the neat demonstrations.

NEWS AND NOTES.

COLLEGE NOTES.

Harvard University.

Several weeks ago, Mr. C. H. Davis, C. E., of New York, spoke before the Electric Club on "Practical Electrical Engineering." Mr. Davis gave many valuable suggestions in regard to the choice of the proper size of dynamos and engines for an installation, methods of wiring, choice of lamps, switches, etc. The necessity of looking carefully after all the little details of an installation was especially dwelt upon.

The pupils of the Manual Training School gave public exhibitions on Friday evenings in March. There was a large attendance each time. The Harvard contingent distinguished itself as usual. The new Thomson-Houston plant just installed made an excellent showing.

It has been found that if telephone wires are connected to the gas pipes at the Jefferson laboratory, the ticking of the clock at the Harvard Observatory—about two-thirds of a mile distant—can be heard. The sound is rather faint, but it is unmistakeable.

The Electric Club has recently received a number of fine catalogues, among them one bound in morocco and gold, from the Fraser & Chalmers Co. of Chicago. The club is making a special feature of this collection of catalogues, and hopes to have it the finest and most complete in America. It is intended to have represented every dynamo, lamp, engine, boiler, etc., used in two or more central stations anywhere in the United States. In addition there will be catalogues of all kinds of supplies, telegraph and telephone apparatus, etc. The club believes this collection will be very valuable, both to itself, and to the companies represented.

Professor B. O. Pierce has somewhat recovered from his illness, and has gone to the White Mountains to regain his strength.

TELEGRAPHIC FAST SENDING TOURNAMENT.

The National Fast Telegraphing Tournament, organized so ably by Mr. Fred. Catlin, of "Catlin grip" fame, takes place on Thursday afternoon and evening, April 10, at Hardman Hall.

There will be three distinct classes in the tournament, the first being open for all, with three prizes of $100, $70 and $30; the second, also open for all, barring those operators who have made a better record than eleven minutes, with three prizes of $85, $65 and $30. The third is for the ladies' class free for all, with prizes of $50, $40 add $20. A very interesting feature will be an "Old Timers' Class," open to those who were in the service prior to 1865, and in which will be two prizes, $50 and $40. Additional prizes of small amounts will be awarded to the sender and receiver who shall make the cleanest work and the best copy, regardless of speed.

It is expected that all previous records will be broken in the coming tournament. In 1885 J. W. Roloson won the championship with a score of 10m. 32s., Wm. Gibson came second with a score of 500 words in 10m. 57s., and F. H. Kihm third, in 10m. 38s. Although Kihm was speedier than Gibson by a few seconds, the latter's work was slightly better. The 500 words then used contained 2,334 Morse characters, 15 periods and 4 commas, a total of 2,368 characters, or an average of 230 characters to the minute. Mr. W. P. Phillips estimates that the winning speed involved 19 movements of the hand per second.

KINDLY GREETINGS.

The Electrical Engineer, the oldest journal of its class in America, and long and favorably known in its monthly form, is to be converted into a weekly publication from the date of April 1 next. Mr. T. Commerford Martin and Mr. Joseph Wetzler, both well and widely known in connection with electrical journalism, will be connected with the Engineer in its new form, and their names in connection with those of Mr. F. L. Pope and G. M. Phelps are a sufficient warrant of the character of the re-organized journal.—*Engineering News.*

The Electrical Engineer has been published some years as a monthly and has made an excellent reputation as a high-class technical journal. It is now to appear weekly, the first weekly issue to be out April 2. It is the purpose to enlarge the field covered, without lowering the scientific standard of the journal. Mr. T. C. Martin, past president American Institute of Electrical Engineers, and Mr. Joseph Wetzler, one of the Managers of the Institute, have both taken editorial charge. These gentlemen have been for some years editors of the *Electrical World*, and to their excellent, untiring and loyal work very much of its success is due. They will take the same qualities to their new field, and we have no doubt that there, too, they will win success.—*Railroad Gazette.*

The Electrical Engineer is probably the most thoroughly scientific electrical journal published this side the Atlantic, and has become as necessary to the student of electrical matters as some other publications which devote more attention to the electrical news of the hour. Beginning with April 2, it will be changed from a monthly to a weekly issue. T. Commerford Martin, past president of the American Institute of Electrical Engineers, and Joseph Wetzler, both of whom have been identified with the editorial conduct of the *Electrical World*, have retired from that journal, and taken charge of the Engineer. They will enlarge the field covered without lowering the scientific standard of the journal.—*Providence Journal.*

THE MAGNETIC ROTATION OF POLARIZED LIGHT.

In a recent number of the *Philosophical Magazine* H. du Bois describes a valuable research on Kerr's phenomenon, undertaken with the special object of showing the intimate connection between the rotation of the polarized light and the intensity of magnetization of the body at the polished surface of which the light is reflected. Ellipsoidal-shaped specimens of different metals were taken, the end of each being cut off and the surface polished so as to form a mirror. To avoid optical complications the light was always reflected normally on the surface. The amount of rotation produced by reflection was found to be proportioned to the intensity of magnetization when the mirror was cut perpendicularly to the lines of force. When the axis of the mirror was inclined to the lines of force the rotation was proportional to the cosine of the angle of inclination. The verification of this law for five different angles is important, as it has not been done before. Experiments were also made to determine the influence of temperature, with the result that for a range of over 200° C. the ratio between rotation and the magnetic intensity was unaltered for either cobalt, iron or steel. Some slight differences in the case of nickel are easily explained by the fact that the intensity of magnetization just behind the mirror differed from the measured mean intensity of the magnetized body. That the effect depended purely on magnetization, and not on the method by which it was produced, was shown by obtaining the same results when residual magnetism alone was used. The variation of rotation with color was also investigated. The intimate connection between Kerr's phenomenon and Faraday's magnetic rotation is clearly shown by these experiments. The rotation produced is dependent on the intensity of magnetism immediately behind the mirror, and is probably due to the rays of light penetrating a slight distance into the material before the act of reflection is completed.

THE CONDUCTIVITY OF VACUUM.

Dr. James Moser, of the physical laboratory of the Imperial University of Vienna, brought the following interesting facts before a recent meeting of the Imperial Academy of Sciences. A Geissler tube was enclosed in another glass tube connected to a mercury pump and placed near to a powerful indnction coil serving as a source of electrical oscillations, when the following effects were noticed :—1. When the outer tube was at atmospheric pressure, the inner tube was light blue, and the outer one unaffected. 2. This appearance was reversed as soon as the air in the outer tube was sufficiently exhausted; then the inner tube was dark, the outer one becoming conducting and exhibiting a reddish glow.

The question remained, What would happen if the air in the outer tube were still further exhausted? It is known that the discharge of Geissler tubes with electrodes is diminished at a very high vacuum. The cause of this diminution has been much discussed. Some hold the cause to be the non-conductivity of the vacuum; others attribute it to surface resistance at the electrodes. This experiment makes it easy to decide between these two theories, for there can be no question of electrode resistance, as there are no electrodes. The exhaustion was, therefore, carried still farther. The outer tube then again became non-luminous and the inner one glowed as at first. Thus it was shown that the more complete vacuum has no screening effect, and loses its conducting power.

THE TARIFF ON MICA.

Mr. J. S. Moore, the free trade polemic, has a recent letter in the *New York Times*, in which he thus delivers himself with regard to the tariff on mica: "It has been my good luck to receive the controversy of the stovemakers and the mica producers on the coming McKinley Tariff bill. The subject lies in a nutshell. Mica is the crudest kind of a mineral product. It is used by stovemakers as a sort of "fire window" in a stove, and it is still more used now in the electrical manufacture of dynamos and motors. In other words, it is a necessity for actual manufacturing purposes. Unfortunately for the manufacturers who are obliged to use mica, we have a few crazy mica mines in New Hampshire and North Carolina. Hence it is sought to protect the home infant mica mines.

"Mica has always been on the free list, and it is further a peculiar fact that the electrical manufacturers cannot use the infant home-produced mica, even if they were to get it for nothing, whereas, the stovemakers can use the home product. Now, then, it is proposed to tax mica 35 per cent., which will have the effect of taxing the electrical manufacturers 35 per cent. on the use of foreign mica, that they are bound to use, which tax goes into the Treasury, now overflowing with a surplus; and, on the other hand, it will raise the price of home-produced mica 35 per cent., used by the stovemakers, for the benefit of the home producers of mica. This is the innocent little game. True, the tariff swindle on this article is small, but it is so sweet and so ludicrous."

OPERATING TELEPHONE MAGNETOS FROM AN EDISON STATION.

The Chicago Telephone Company now uses commuted Edison current for operating the magneto bells on its lines. A commutator operated by a small water motor is employed to alternate the current. The two brushes of the commuting device are connected with the positive and negative wires of the Edison mains. The neutral wire runs to one segment of the two-part commutator. Between the plug terminal of the neutral wire and the commutator, in series, are the primary coil of a transformer of special design and an incandescent lamp. One end of the secondary coil of the transformer is connected to ground and the other runs to the switch-board in the exchange. As the commutator is kept in motion by a water motor one segment, which is connected with the primary of the transformer, comes alternately into contact with the + and — brush. In this manner the direction of the flow of current in the primary is changed at every revolution. The result is that an alternating current of like character is induced in the secondary coil. As one end of this coil is grounded and the other runs to the switch-board, it is only necessary to press the key to send an alternating current over a line to ring the magneto bells.

OBITUARY.

George D. Allen.

It is with deep regret that we announce the death, on March 28, of Mr. George D. Allen, the well-known and highly-esteemed secretary and general manager of the Excelsior Electric Co. The cause of death was pneumonia, and the news came with staggering suddenness to his associates and friends. Mr. Allen was only 46 years of age and seemed good for many years of hard work. His direct connection with the electrical business was of many years standing. If we are not mistaken, he sold the first Brush machine or plant in this part of the country. He started the Arnoux-Hochhausen Co., and a little later, in August, 1881, with Mr. Hochhausen, formed the Excelsior Electric Co., which is to-day not only one of the oldest corporations in the electric light and power field, but is, after a struggle in which many companies that came into existence later have lost ground or gone out of existence, successful, substantial and progressive. It goes without saying that this state of affairs has been largely due to Mr. Allen's sterling qualities and to the good fortune that attended the company as later changes were made in the personnel of its direction, himself continuing as secretary and general manager throughout.

The funeral services were conducted at Mr. Allen's residence on Washington avenue, Brooklyn, by the Rev. Dr. DeWitt Talmage, and the interment took place in Greenwood cemetery.

Benjamin F. Thurston.

The death of Mr. B. F. Thurston, of Providence, R. I., last month, at the age of 60, removed the leading patent lawyer of the country, and created a deplorable vacancy in the higher ranks of the legal profession. As a consulting lawyer Mr. Thurston was probably without an equal, and of late years his whole work has been done in that capacity. Mr. Thurston was one of the most valued counsel of the Edison company, and not long before his death he had been engaged in working up for them the arguments in connection with the fundamental Edison filament incandescent lamp patents. He was also retained by the Sprague company as consulting lawyer on some of their leading patents; and, in fact, it may be said that he figured in nearly every important electrical litigation of the last decade.

LEGAL NOTES.

INTERFERENCE—STANLEY vs. SLATTERY.

The interference which has been pending for a long time before the Patent Office, between a patent granted to M. M. M. Slattery, of the Fort Wayne Electric Co. and a subsequent application of William Stanley, Jr., of the Westinghouse company, for the method now extensively used of operating converters with alternating currents in multiple arc, has been decided in favor of Stanley on every point. It was established that the invention was made and reduced to practice by Stanley in a full-sized experimental working plant at Great Barrington, Mass., in the spring of 1886, some time before Slattery commenced his experiments.

CHAFFEE vs. TELEPHONE AND TELEGRAPH CONSTRUCTION COMPANY.

In Chaffee *vs.* Telephone and Telegraph Construction Co. Supreme Court of Michigan, it was held that one who erects a building by the side of telegraph and telephone wires, which are on his own land, makes no protest against the maintaining of the wires, allows his tenant in the building to use one of the wires for business purposes, and thus goes on for years, making no complaint whatever, cannot recover of the owner of the wires for losses on the building by fire which might have been averted but for the hindrance to the work of the firemen, occasioned by the wires. This judgment was rendered by a divided bench. Campbell, J. dissenting, said that while delay in complaining might cut off a right to sue in equity, "nothing short of a statutory limitation can bar a suit at law; and where a wrongful entry or intrusion is made without license no license can be legally presumed from inaction. It is not in the power of a city to license any one to damage or encroach on the property of individuals, and no jurisdiction can be based on it."

INVENTORS' RECORD.

CLASSIFIED LIST OF UNITED STATES ELECTRICAL PATENTS.

Issued April 1, 1890.

Alarms and Signals:—*Electric Indicator*, 424,725 and 424,726. *Automatic Fire Alarm*, C. A. Cox and J. F. Cox, 424,860.

Clocks:—*Double-Faced Electric Clock*, E. W. Lindeman, 424,929.

Conductors, Insulators and Conduits:—*Electrical Insulator*, T. S. Reed, 424,575. *Electrical Conductor*, J. A. Barrett, 424,751. *Ventilating System for Electric Subways*, W. Gee, 424,778.

Dynamos and Motors:—*Electric Motor*, Leo Bock, Jr., 424,585. *Regulation of Electric Motors*, S. Bergmann, 424,595. *Electric Motor*, L. T. Smith, 424,734.

Lamps and Appurtenances:—*Marine Electric Light*, A. G. Donelly, 424,544. *Arc Lamp*, R. H. Beach, 424,752. *Arc Light*, J. Dulait, 424,866.

Measurement:—*Method of, and Apparatus for, Measuring Alternating Currents of Electricity*, W. Lowrie, C. J. Hall and H. W. Kolle, 424,891.

Miscellaneous:—*Lightning Arrester*, O. P. Loomis, 424,562 and 424,563. *Choking Electro-Magnet*, L. Gutman, 424,606. *Safety Device for Electric Circuits*, C. G. Young, 424,665. *Electro-Magnet*, G. D. Clarke, 424,703. *Electric Trap*, F. Scherer, 424,729. *Electric Switch*, C. S. Van Nuis, 424,739. *Magnetic Pen-Holder*, E. A. Hill, 424,786. *Electro-Medical Belt*, W. J. Shelton, 424,827. *Electrical Heater*, J. V. Capek, 424,921. *Electrical Cooking-Stove*, J. V. Capek, 424,922.

Railways and Appliances:—*Method of Operating Electric Railways*, R. M. Hunter, 424,607. *Suspended Switch and Travelling Contact for Electric Railways*, C. J. Van Depoele, 424,695. *Electric Locomotive*, J. F. McLaughlin, 424,810. *Electric Railway Motor*, F. A. Perret, 424,818. *Electric Railway*, E. M. Bentley, 424,845. *Electric Railway*, F. O. Blackwell, 424,848. *Electric Railway*, W. H. Knight, 424,887 and 424,888. *Contact Device and Switch for Electric Railways*, C. J. Van Depoele, 424,910. *Electric Railway Motor*, 424,911. *Electric Railway*, R. M. Hunter, 424,928.

Secondary Batteries:—*Electrode for Secondary Batteries*, J. F. McLaughlin 424,809.

Telephones and Appliances:—*Tablet for Telephones*, John B. Morris, 424,493. *Pneumatic Telephone*, J. G. Moreau, 424,684. *Graphophone*, J. H. White, 424,914.

.... ELECTRICITY may possibly be a form of matter—it is not a form of energy. It is quite true that electricity, under pressure or in motion, represents energy, but the same thing is true of water or air, and we do not therefore deny them to be forms of matter.—*Oliver J. Lodge.*

.... SCIENCE has attained a development and a stature and a power that give her the ability to assume her place in the great scheme of civilization. Hereafter she will direct and will lead.—*Professor Robert H. Thurston.*

TRADE NOTES AND NOVELTIES

AND MECHANICAL DEPARTMENT.

AN OLD SYSTEM REPLACED AT ALLEGHENY, PA.

The managers of the Federal Street and Pleasant Valley Street Railway, of Pittsburgh, Pa., which has been operating twenty-five motor cars on the Sprague electric system for some time, are so well pleased with the operation of the cars on that road that they have ordered an additional equipment of fourteen motor cars. Each of these cars will be equipped with two Sprague improved railway motors. This road now extends in the city of Allegheny, over the line of the early electric railway on University Hill, which used the Bentley-Knight system with underground conduit, and was one of the first installed upon that system. The regular method of overhead contact is now used on this section of the road as well as upon the rest of the line, and the conduit is no longer used. The grades surmounted by the electric cars upon this road are quite severe, being in one place about 12½ per cent., the length of the grade being over a mile.

With the old electrical equipment, this grade was considered too steep to be ascended in the ordinary manner, and at the steepest part a rack was used between the tracks, in which a pinion connected with the motors engaged, in order to secure the necessary traction. With the new equipment this arrangement is found to be unnecessary, and the Sprague cars have no difficulty in ascending the grade with the aid of no other traction than that which the wheels secure from the rails themselves.

There over thirty cars in regular operation upon this railway line.

A THOMSON-HOUSTON MILL TRAMWAY AT LAWRENCE, MASS.

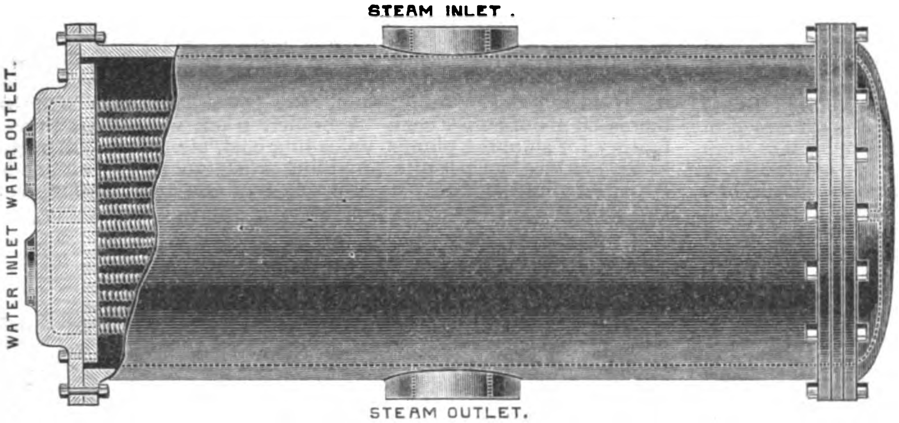
Conclusive proof of the fact that electricity can be used to advantage for mill tramways is evinced in an installation at the Washington Mills, Lawrence, Mass., which has recently been completed by the Thomson-Houston Motor Co. The tramway is used exclusively for carrying coal from the coal pockets to the boiler-room, a distance of about 400 feet. The track is level the entire length, and for the most part straight, there being but two curves; an S-curve just after leaving the coal pockets, and a similar one, though a less sharper turn, where the track enters the boiler-house.

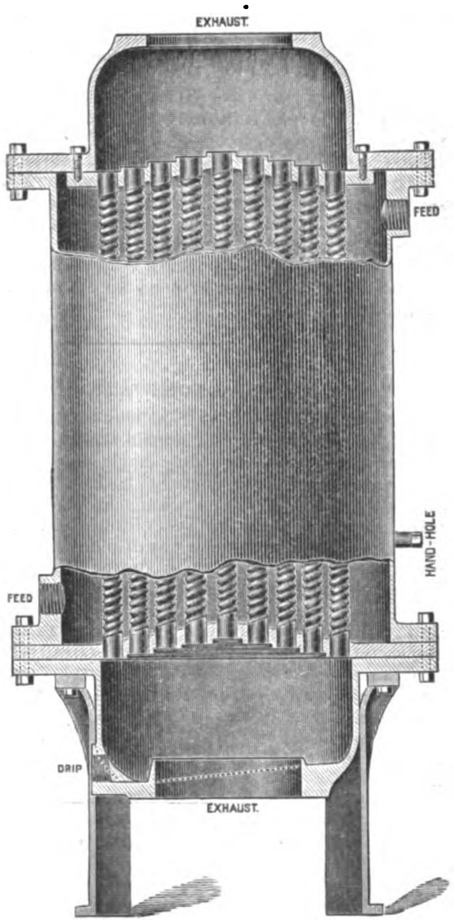
In the electrical construction the overhead system has been used, brackets being employed to support the trolley wire, which runs in height from twelve feet where all is clear, to six feet where the track passes underneath a belt box between two of the mill buildings, the springs on the trolley arm being so adjusted as to maintain an even pressure of the trolley against the conductor irrespective of its height. The current for the operation of the motor car is supplied from a 110 volt dynamo which is used for mill lighting, the rails and a supplementary ground wire being used for the return circuit.

The car equipment consists of one ordinary dump coal car, and one platform car provided with one three h. p. 110 volt series wound motor geared to the car axle, and capable of developing sufficient power to haul a load of 5,000 pounds at a rate of six miles an hour. At one end of the car are placed two levers, one for the special type rheostat used for governing the motor, the other for the reversing switch. Both of these as well as the brake handle are under the immediate control of the operator, who stands upon the platform in front. The floor of the car is made so that it can be readily removed to allow an easy inspection of the motor and appliances, which, though covered with a thick coating of coal dust at all times, have not failed to operate satisfactorily since the tramway was first put in operation.

THE WAINWRIGHT CONDENSER AND FEED-WATER HEATER.

It has now come to be generally recognized that for the economical operation of electric plants, whether for lighting or power purposes, every particle of the available heat in the coal must be utilized. The condenser and the feed-water heater have therefore taken a prominent place in electric central stations, and among the builders of such apparatus who have paid special attention to this department in steam economy are the Wainwright Manufacturing Co., of Boston, Mass. The condenser made by this firm is illustrated in the accompanying engraving, Fig. 1, and embodies the spirally corrugated tube. This entirely overcomes all expansion and contraction, and allows both ends to be made rigid and absolutely tight. The strength of the corrugated tube being three times that of the plain, enables a tube of thinner gauge to be used, which fact, combined with the increase of surface due to the corrugations, and the rotary motion imparted to the water in passing through the tube, renders its efficiency greatly superior to that of the plain tube.





Figs. 1 and 2.—Wainwright Condenser and Feed Water Heater.

The copper tube feed-water heater, also manufactured by the Wainwright Company, is shown in Fig. 2. In this improved heater the water is outside of the tubes, the steam passing through the latter. There is thus afforded a large water space and consequently a comparatively slow passage through the heater, giving the impurities in the water a chance to settle. Another excellent feature of this heater is the method of dripping, the condensed water gravitating around the bottom to the drip opening and out.

Cast iron shells are used on all heaters up to, and including, 300 h. p., which are practically indestructible. Above 300 h. p. steel shells are used. No interior piping whatever is employed in this heater, which can be used horizontally by removing the legs. The heater is guaranteed to deliver the feed-water at a temperature of 200° to 212° Fahrenheit, and to be most carefully constructed.

The Wainwright company also manufacture a variety of other steam appliances, among them being various types of corrugated expansion joints for steam pipes, heaters for compound engines, the Harvard pump regulator, and the Bray & Nickerson automatic water gauge valves.

CARBON DEPOSIT IN A BLAKE TELEPHONE TRANSMITTER.

At a recent meeting of the London Physical Society, Mr. F. B. Hawes read a communication on the above subject and exhibited photographs of the interior portions of a transmitter on which the deposit had taken place. These portions consist of a metal diaphragm, a highly polished carbon button, and a platinum contact piece carried by a german-silver spring placed between them. The diaphragm presented a mottled appearance due to the deposit, but the part which had been behind the german-silver spring seemed comparatively clean. The deposits on the carbon button and german-silver spring were much less dense than that on the exposed parts of the diaphragm, and the space near the point of contact between the platinum and carbon was free from deposit. The deposit was fairly adherent, considerable rubbing being necessary to remove it, and on examination under the microscope particles of copper and metallic crystals could be seen. The author believes the deposit due to some kind of bombardment of carbon particles, but was unable to say why it should occur, or why the varnished diaphragm should receive the greater deposit, although it was further from the carbon than the german silver spring.

In the discussion which followed, Mr. C. V. Boys said the photographs reminded him of a phenomenon he observed some time ago on a glass sheet, against which one terminal of a dry pile had been resting for some weeks. Just as on the carbon button, the glass near the point of contact was clean, and had a comet-shaped deposit formed around it. He could offer no explanation of the appearance.

ARTISTIC ILLUMINATION AT A WEDDING.

One of the principal features of the wedding of Mr. Solomon Frank's daughter at Concordia Opera House, Baltimore, was the electric illumination. The hall was tastefully decorated with house plants. In the centre of the hall, and directly under the main chandelier, were potted plants in the shape of a Maltese cross, which extended up to the chandelier. Among the plants were placed different colored incandescent lamps, in shades and ground glass globes. Around the main chandelier were placed tinted globes representing all kinds of fruit. In each corner of the room there was a pyramid of plants illuminated with colored lights and ground glass globes. The front of the stage was decorated in the same manner. The curtain, behind which the musicians were ensconced, was made entirely of green leaves. It was gracefully draped and had a border composed entirely of incandescent lights. The appearance of the hall was that of a large flower garden on a bright moonlight night. The illumination was carried out by the Electrical Construction Company, Baltimore, C. W. Huntington, manager.

"FIBRONE" AND "PLASTICON."

These are two new insulating materials which have recently been brought out by the Fibrone Manufacturing Co., of 35 Warren street, this city, and which are said to possess high insulating qualities. The "fibrone" is claimed to be a perfect non-conductor and to be absolutely water-proof and proof against the weaker acids; it can be made to withstand any strength of acid, and all action of alkalies, and is, therefore, particularly useful for battery jars and covers. It does not flake off, crack, expand or contract under ordinary temperatures, and for special purposes can be made to withstand a high degree of heat, and can even be made absolutely fire-proof. It may be sawed, planed, drilled, tapped or turned in a lathe, in the same way as hard rubber, and made heavy or light; and also supplied in any color, and in imitation of any natural wood, stone or metal.

This material is intended to take the place of hard rubber, taking a high polish and resembling the latter material very closely.

The company also manufacture all kinds of electrical fittings, of their "plasticon," which may be molded, pressed, cast or turned into any shape. Both materials can be furnished in any form, such as sheets, tubes, rods, bell boxes, rosettes, etc.

ORDERS FOR SHALLENBERGER METERS.

The Westinghouse Electric Co. has received an order for 750 Shallenberger meters of various sizes, which is the largest single order for these instruments that has come to the company since it placed the meters on the market. The order comes from across the Atlantic, it having been placed by the Metropolitan Electric Supply Co., of London, England, which several months ago decided to adopt the Westinghouse alternating current system for use in its large central stations in the great metropolis. Shortly after getting the first machinery started, the London company made a trial of the meters, and, being satisfied with the result, immediately ordered 350 of them. It has now seen fit to supplement the capacity of these 350 by an additional 750 meters, and when the latter order is received in London and put in use, 1,100 meters of the Westinghouse manufacture will be employed there. The Westinghouse Electric Co. is, naturally, more than a little pleased at this evidence of appreciation for their machinery on the part of the English company. The Metropolitan Electric Supply Co., by the way, first ordered 10,000 lights capacity in dynamos from the Westinghouse company and about the first of February last placed a second order, for the purpose of increasing its capacity to 25,000 16-candle power lamps.

WESTINGHOUSE LIGHTING PLANTS.

The Westinghouse Electric Co. reports the following very good showing in central station business for the month of March, 1890: *Incandescent.*—Tampa, Fla., 500 lights, increase; Bluff Point, N. Y., 1,500; Kewanee, Ill., 750; Warren, Ohio, 750; Rochester, Pa., 500; Shelby, N. C., 500; Methuen, Mass., 750; Nashville, Tenn., 3,000, increase; New York, N. Y., 1,500, increase (Mt. Morris Co.); Canton, Mass., 750; New York, N. Y., 15,000, increase (United E. L. & P. Co.); Hoquiam, Wash., 750; Boston, Mass., 3,000, increase; Fort Collins, Col., 750; Girard, Kan., 750; Auburn, Me., 1,500, increase; Wilmerding, Pa., 1,500. Total, 33,750 lights. *Arc.*—Warren, Ohio, 105; Joliet, Ill., 65; Methuen, Mass., 40; Nashville, Tenn., 540; New York, N. Y., 125, increase; Hoquiam, Wash., 50; Cumberland, Md., 45; Girard, Kan., 25; Boston, Mass., 125, increase; Harriman, Tenn., 60; Canton, Mass., 35. Total, 1,215 lights.

A NEW STEAM PUMP FACTORY.

Bids for the new steam pump factory of the Deane Steam Pump Co. will soon be advertised for, as the plans are about finished. The plant is to be located on a lot 200x500 feet. It will consist of five large buildings, with numerous wooden buildings for coal, clay, supplies, etc. The machine shop will be 300x80 feet, with one floor and necessary galleries. The foundry building will also occupy one floor and will be 194x76 feet. The pattern house will be 106x38 feet, and will have three floors. The blacksmith shop, boiler room, engine and testing room will occupy a building 177x34 feet, one floor. An office and storeroom of two stories will be 96x50 feet. It is probable that steam power will be used entirely. The facilities of the Deane company will be increased about 50 per cent. A branch track will be run to the factory for shipping pumps, unloading coal, etc. Work will begin as soon as weather permits, providing satisfactory terms are made with the contractors. The company now employs 235 men, and this number will be largely increased.

AN ELECTRIC MOTOR IN A THEATRE.

A novel and interesting application of electric power has recently been made in New York. In one of the theatres, a spectacular play requires the presentation of a horse race on the stage. In order to keep the race constantly in view of the audience, the platform upon which the horses race is endless, and kept constantly moving over a pair of rollers at each end. When the question of motive power was considered, a Sprague electric stationary motor was selected for the work. This is belted to a system of counter-shafting which reduces the speed to that required by the rollers of the movable platform. This is an example of the varied use to which electric motors are now being applied. When the manufacturers of the Sprague motor made the statement, a year or so ago, that their motors were used in more than 130 different industries, the statement seemed almost incredible, but the convenience of the electric motor and its wide range of adaptability to all classes of work, have made it almost a necessity in places where no other motor could be used.

THE TELEPHONE.

THE town of Hilo, Sandwich Islands, is said to have a more complete and universal telephone service than any town of the same size in Great Britain.

AN ELECTRICAL DRAWBRIDGE AT WILMINGTON, DEL.

An iron drawbridge over the Christiana river in Wilmington, Del., is about to go into service, operated by electricity. The draw is 250 feet long and 34 feet wide, with a roadway and two footways. The total weight is about 200 tons. The motor is by the Thomson-Houston Co., and at a recent test turned the draw completely around in 1¼ minutes. The bridge is lighted with 14 incandescent lights, from the same circuit that supplies the motor. The bridge was designed by Mr. Albert Lucius, of New York, and built by Messrs. Dean & Westbrook, of New York. The total cost, including the motor, was $65,000.

THE SHORT ELECTRIC RAILWAY SYSTEM FOR ROCHESTER, N. Y.

The H. Sellers McKee syndicate, which controls the entire Rochester, N. Y., system of street railways, has just let an immense contract to the Short Electric Railway Co., of Cleveland, Ohio. The contract calls for 100 cars with double motors and 1,100-h. p. generators. Sixty-eight miles will be covered by the system. It is one of the largest contracts ever let for an electric railway system and amounts to $360,000. The contract for the Johnstown Electric Street Railway Co. was let on Monday to the same company. Ten miles will be covered and ten cars have been ordered.

SILK TOWELS FOR DYNAMOS AND MOTORS.

The Royal Silk Manufacturing Co., 2 and 4 Stone street, are manufacturers of non-combustible silk machine toweling, which is specially intended to replace cotton waste, rags, etc., in cleaning machinery. These silk towels are not combustible, even when hot and oily, and a great feature is that they can be washed thirty or forty times. They have great absorbing powers. Practically they are 50 per cent. cheaper than waste. They ought to find great favor for dynamo and motor work.

THOMSON-HOUSTON WESTERN BUSINESS.

The following is a list of the sales of apparatus of the Chicago office of the Thomson-Houston Electric Co., for the month of March, 1890.

ARC.—Fort Smith Gas Lt. Co., Fort Smith Ark., 35 lts; Freeport Elec. Lt. Co., Freeport Ill., 50 lts; John Featherstone & Son, Chicago, Ill., 20 lts.; Osceola Gravel Mining Co., Osceola, Nev., 3 lts; University of Notre Dame, South Bend, Ind., 12 lts; Manitou Elec. Lt. Co., Manitou, Col., 3 lts; A. W. Wright, Alma, Mich., 30 lts; Freeport Elec. Lt. Co., Freeport, Ill., 50 lts; B. F. Draper, Ligonier, Ind., 50 lts; Mt. Clemens Elec. Lt. Co., Mt. Clemens, Mich., 30 lts; Laredo Improvement Co., Laredo, Tex., 50 lts; Laredo Improvement Co., Laredo, Tex., 50 lts.

INCANDESCENT.—Auburn Mining Co., Auburn, Ind., 300 lts., alternating; John Kranz, Chicago, Ill., 300 lts., direct; W. C. Clark,, Chicago, Ill., 300 lts., direct; Manitou, Elec. Light Company, Manitou, Col., 300 lts., direct; A. W. Wright, Alma, Mich., 650 lts., alternating; G. F. Culmer, & Bro., Salt Lake City, Utah, 150 lts., direct; Laredo Improvement Co., Laredo, Tex., 1,300 lts., alternaitng; National Electric Construction Co, Chicago, Ill., 300 lts., direct.

MOTORS.—American Press Asso., Omaha, Neb., 5 h. p. Motor; J. T. Robinson, Notion Co., Omaha, Neb., 5 h. p. Motor.

THE SPRAGUE EQUIPMENT COMPANY.

The Sprague Equipment Co., the Rialto, Chicago, in their fine new offices have on exhibition a large 440 volt Sprague motor for mining purposes, located in the entrance corridor and close by is placed an Edison generator of latest type. A handsome board of antique oak with billiard cloth centre containing samples of all the latest overhead railway appliances, including a new and improved trolley wire insulator, overhead circuit breakers, pull-off brackets, centre curve insulators, improved trolley wheel and a special raw-hide pinion, also attracts much attention. Last but by no means least is Mr. J. L. Barclay's "Electric Extravaganza" consisting of an elegantly finished antique bronze fireplace set in handsome tile work, containing a number of incandescent lamps with ruby globes embedded in cut glass prisms. This is situated in Mr. Barclay's private office, and is quite a work of art and beauty.

The Sprague Company have just completed the equipment of the Sioux City Street Railway Company's line in Sioux City, Ia., with 25 cars over 15 miles of track. The following telegram signed by James F. Peavey, President of the road has just been received "Started trial car yesterday. Run most satisfactory. We are very much pleased," and further in a letter he says "I am more than pleased with our construction all the way through, which is of such a character that all connected with the Sprague Equipment Co., can point to it with much pride. Our citizens are very enthusiatic."

HOLMES, BOOTH & HAYDENS.

MR. H. P. LUCAS, of the above house, has accepted a position as assistant treasurer and purchasing agent with the Northwestern Electric Construction and Supply Co. of St. Paul. Mr. Lafayette Cole, secretary and manager of the Peoria, Ill., Electric Light & Power Co., has resigned and accepted a position as salesman with Holmes, Booth & Haydens, in the place of Mr. Lucas.

WALWORTH STEEL AND IRON POLES FOR ELECTRIC RAILWAYS.

The Walworth Manufacturing Co., of Boston, are in receipt of some very large orders for their well-known iron and steel poles for electric railways. Among them are orders from the Lindell Railway Co., of St. Louis, for 886 centre bracket poles, extra strong, having butts 8 inches in diameter. These poles are the heaviest ever made for that purpose, and are designed so that a runaway team or fire engine coming in contact with them will have no damaging effect. The St. Paul City Railway Co. have also ordered about 1,000 poles, Minneapolis Street Railway Co., 600 poles, and the United Electric Railway, of Nashville, Tenn., 480 poles. Altogether the Walworth company have orders on their books for over $80,000 worth of poles, and are preparing for a very heavy year's business.

OPENING OF THE WOMAN'S EXCHANGE ELECTRICAL EXHIBITION.

The above exhibition, including Mr. Edison's famous Paris Exposition collection of inventions, was opened at the Lenox Lyceum on April 7, by Mr. F. R. Coudert, and by Professor C. F. Brackett, who made an address on the subject of electricity. The exhibition embraces many novel features, and will probably be a great attraction. It will continue until May 15, and is open afternoon and evening, Sundays excepted.

Among the special exhibits are a beautiful central tower of incandescent lights, with streamers; a magnificent telephone exhibit by the telephone companies, so that various operatic performances going on in the city can be heard; long distance telephone lines, one of which brings the roar of Niagara into New York city for the first time; a phonographic dolls' theatre; "A Peep Into the Twentieth Century;" an electric railway, and a number of phonographs. These, and many other novelties are supplemented admirably by the great exhibit of Edison's inventions.

Mr. A. B. De Frece, the manager, is to be congratulated on his success in bringing so fine an electrical exhibition together.

NOTES FROM GERMANY.

However much Germany may in general be behind America in her application of the electric light, a notable exception must be made of Berlin. While the built up portion of the city is fairly well lighted, the principal street, the beautiful "Unter den Linden" is at night almost literally as bright as day. This street, 1,000 meters long and 60 wide, is furnished with three rows of electric lamps, two along the sides and one in the middle between the lindens. Berlin can now hold its own with any city in America as regards completeness of its central station, excellence of its arc lamps (Siemens), and thoroughness of its illumination at night.

BIDS FOR NEW YORK STREET LIGHTING.

Bids for gas and electric lighting for the city for another year were opened April 7 by the Gas Commission at the Department of Public Works. Mayor Grant, Comptroller Myers and Commissioner Gilroy, composing the commission, were all present.

The bids of the electric light companies, when opened, exhibited a uniform advance in the prices demanded over last year. Representatives of the companies present declared that the increase was made necessary by the increased cost to them of the subway system of conduits. The United States company bid for 314 lamps at 39, 41 and 42 cents, respectively, per night each. The Brush company, for 337 lamps, asked the same prices. For 175 lamps the Mount Morris company asked for part 39 cents and for others 42 cents. The Harlem Lighting company wanted 39 cents per night for 166 street lamps and 50 cents for 19 lamps in Mount Morris Park. The East River company asked 42½ cents for 226 lamps.

The total number of lamps bid on is 1,237, or 109 less than last year, the cutting down of the wires having removed that many. The prices are about 15 per cent. higher than those of last year. The bids were referred to Secretary McCormick to tabulate and report on.

WOODHOUSE & RAWSON UNITED, L'TD.

Owing to the rapid increase in the importance of their South African trade, the above company have decided to open a branch warehouse and showroom in Johannesburg, which will be under the management of Mr. R. Lewis Cousens, M.I.E.E., late electrician to the Kimberley Town Council, who is thoroughly acquainted with the requirements of the South African States, and who will have the assistance of a competent staff. Special attention will be paid to the carrying out of such work as the lighting of cities, hotels, mines, docks, railways, etc., the transmission of power for running stamps, tramways, light railways, telpher transport, etc., while it is intended that the depot itself shall be stocked with a most complete assortment of engineering and electrical requisites of the very latest types, and manufactured with a view to the special requirements of the country. A detailed telegraphic code has been arranged with the head office in London, and in the event of any goods being ordered which do not happen to be in stock or on their way, they can be cabled for and shipped within a fortnight.

MANUFACTURING AND TRADE NOTES.

The Westinghouse Electric Co. has recently been awarded the contract for a 3,000 light plant, of the alternating current system, in Lexington, Ky.

The Phœnix Glass Company report an excellent demand for electric lighting glass ware, and Mr. A. H. Patterson finds business opening up in good shape for the season ahead.

Gas Fixture Combination.—The well-known and substantial concerns, Archer & Pancoast Manufacturing Company, and Oxley, Giddings & Enos, have consolidated their electrical and gas fixture business.

The Central Electric Co., 116 and 118 Franklin street, Chicago, are very busy shipping supplies to all parts of the country. Okonite is in specially large demand. In pins and brackets, which they manufacture very largely, business is very lively.

Mr. P. C. Burns, of St. Louis, has been a reent visitor in New York, and reports the Findlay Glass and Carbon Co. as being busy making porcelain cut-outs and cut-out rosettes for electric lighting purposes, in addition to their regular line of carbon batteries, jars, insulators, etc.

The Wheelock Engine Co., Worcester, is now located in its new factory building at South Worcester. The steady increase of business has compelled the erection of this fine structure. An unusually well constructed engine shop has been put up, being light, airy and convenient.

The Pumpelly Storage Battery and Electric Motor Co., Chicago, are meeting with great success with their cells and are filling large orders right along for the sub-companies of the North American Phonograph Co., They have just shipped 100 cells to San Francisco, where the local company are already using several hundred.

George Cutter, 80 Adams street, Chicago, the Western agent of the Bernstein Electric Co., has been making a short business trip in the East. He expects to do a large business in the new constant potential lamp for incandescent lighting, which that company has recently placed upon the market. The demand for his other specialties, especially the combination tin shade, is very brisk.

Lowell Wrench Co.—The lag screw wrench recently introduced by the Lowell Wrench Co., of Worcester, Mass., is meeting with great favor with electric lighting people everywhere. The merits of the wrench itself, combined with the push of the management, have induced a sale that has already exhausted a number of sizes, and the company for a few days found it impossible to fill all their orders.

The Economic Electric Light and Power Co. are making rapid progress with the transition of Reed Brothers' factory at Brockton, into a factory for the manufacture of dynamos, motors, lamps, and all kinds of electric supplies. Within a few days they will commence operations, and will also have a dynamo and incandescent plant in operation in Houghton & Dutton's store in Boston for exhibition purposes.

Mr. Wm. D. McQuesten was a caller last week at our Western office. He is interested in a railroad deal at Aurora, Ill., whereby the old company is to be purchased and re-organized under a new franchise. Fifteen miles of new road will be built and equipped with 25 cars. Aurora is one of the most active Western manufacturing towns and is directly tributary to Chicago. Mr. McQuesten is going to St. Louis, then to Boston and back to New York.

Among the contracts for alternating current apparatus for central station lighting obtained by The Westinghouse Electric Co. during the first two weeks of February are noticed the following: Williamsport, Pa., 750 lights, increase; Butte, Mont., 750 lights, increase; Fort Worth, Texas, 850 lights, increase; Sioux Falls, Dakota, 750 lights; Pineville, Ky, 500 lights; Lexington, Ky., 3000 lights; Creston, Iowa, 750 lights; Shidznoka, Japan, 1,500 lights.

The Southern Electric Co., of Baltimore (Messrs. J. Frank Morrison and Howard Tuxworth), have just secured a charter from the Maryland legislature giving them full power to erect, equip and maintain electric circuits, either ærial underground, or both. The sudden meeting of the stockholders of the Brush Electric Co. of Baltimore, immediately after the granting of this charter, has given rise to various opinions as to what the Southern Electric Co. propose to do.

Brown & Sharpe Manufacturing Co., Providence, R. I., have sent us their neat and compact little pamphlet of "Catalogues and Price Lists" dealing with their machinery, tools and castings, and those of Darling, Brown & Sharpe, manufacturers of U. S. standard rules, cast-steel try squares, standard wire gauges, special appliances of precise measurement, etc. The 200-page pamphlet is a Liebig's extract of American mechanical and engineering skill and experience.

Thackara Mfg. Co.—The appearance of the exhibition rooms of the Thackara Mfg. Co., in their new quarters at 1524 to 1526 Chestnut street, Philadelphia, can be truly said to be a credit to that city. The walls throughout the building are covered with a rich dark material against which the various designs of gas and electric fixtures show off to great advantage. Floor above floor is laden with the richest work in their line, and the whole being lighted by a new incandescent reflector of recent conception makes an appearance truly artistic.

An Alternating Current Plant for Japan.—The first central station electric light plant on the alternating current system for Japan, is about to be established. A corporation of Japanese capitalists in Tokio, has awarded the contract for the apparatus to The Westinghouse Electric Co., of Pittsburgh, Pa., and the machinery, consisting of two 750-light dynamos, exciters, lamps, sockets, switches, cut-outs, etc., will be shipped immediately. The company which purchases this apparatus is also engaged in the installation of a lighting plant for the city of Canton, China.

The Baldwin Locomotive Works, of Philadelphia, made a continuous test of one week's run on a Westinghouse compound engine of 65 h. p. The engine was non-condensing, and was supplied from an independent boiler, and was loaded to about 75 h. p. The gross coal fired under the boiler during the week's run averaged 2.4 pounds per h. p. per hour, which result is an extraordinary performance. This company already had two of the Westinghouse compound engines in their works, and on the strength of the above performance, have placed an order for a third 200 h. p.

The eighth edition of "The Electrician" Electrical Trades Directory and Hand-Book, London, has recently been issued in familiar shape. This useful annual compilation, familiar to many in the United States, comprises carefully prepared lists of corporations, firms and individuals engaged in electrical industries in all parts of the world, whether as engineers, contractors, manufacturers or dealers. In addition to useful tables pertaining to electrical engineering, the new edition has a biographical section, giving some information of eminent men connected with the rise and growth of electrical application, with several portraits.

Lewisohn Brothers, 81 and 83 Fulton street, are the sole agents for M. A. and Arizona copper, and have become well known to the electrical trades for their pure lake copper wire, and copper in other forms for manufacturing purposes. They have recently issued a sumptuous special "perpetual calendar" in leather and ivory, which is of the neatest and daintiest character imaginable. At the top of the dial are perched three birds in a spray of flowers. The dates are movable by knobs at the back, and a steel finger indicates the day of the month. It is, in fact, the costliest trade calendar of the season, and is beautiful enough to grace a boudoir.

Mr. W. M. Donaldson, a very enterprising electrical engineer of Baltimore, has recently entered into the business of distributing electrical energy by means of storage batteries in connection with small motors for household and office use in the cities of Baltimore and Washington. In Baltimore, his batteries are charged by the arc light wires, and in Washington by a Perret dynamo. Mr. Donaldson's business seems to prosper, judging by his recent order on the Elektron Manufacturing Co. for 40 Perret motors for graphophone work. After a series of practical tests Mr. Donaldson has adopted the Perret motor for his work. In some recent tests with this motor on graphophone work, using two volt battery, when recording, the motor took 2.3 amperes, and when reproducing, 2 amperes. With the ordinary 100 ampere-hour storage cell, the motor will drive the graphophone from 45 to 50 hours continuously, which lasts an ordinary business man one month, the battery being then replaced by a freshly charged one and the discharged battery taken to the charging station.

THE
ELECTRICAL ENGINEER.

EDITORIAL ANNOUNCEMENTS.

Addresses.—*Business letters should be addressed and drafts, checks and post-office orders made payable to the order of* THE ELECTRICAL ENGINEER. *Communications for the attention of the editors should be addressed,* EDITOR OF THE ELECTRICAL ENGINEER, 150 *Broadway, New York city.*

Communications *suitable for our columns will be welcomed from any quarter. Discussions of subjects relating to all branches of electro-technical work, by persons practically acquainted with them, are especially desired. Unavailable and rejected manuscripts will be returned only when accompanied by the necessary postage.*

Advertisements.—*We can entertain no proposition to publish anything for pay, or in consideration of advertising patronage, except in our advertising columns. Our editorial columns will express our own opinions only, and we shall present in other columns only such matter as we consider of interest or value to our readers*

VOL. IX. NEW YORK, APRIL 16, 1890. No. 102

Electricity is subject to laws as definite and invariable as those which govern the mechanical motions of the planetary system.—Joseph Henry.

ELECTRIC MUTUAL STATION INSURANCE.

INSURANCE is a very important item to the manager of an electric light or power plant, and has proved a source of considerable trouble and worry. It must therefore be with feelings of pleasure and welcome that central station superintendents hail the debut of the Electric Mutual Insurance Co.. of Boston, with such men as Mr. S. E. Barton and Captain William Brophy at the guiding reins. That all should understand better for what purpose this company has been organized, we quote its own words and claims:—

> Organized for the purpose of insuring *Buildings, Machinery, and Apparatus* used in the manufacture of *Electric Light and Power.*
>
> Insures against *Loss or Damage by Fire* on *Central Stations: Building and Contents* under "*Blanket Form.*"
>
> Examines stations, upon application, and suggests improvements necessary to secure minimum rates.
>
> Employs skilled electrical inspectors who periodically inspect all stations insured by the Company, in order to reduce the fire hazard.
>
> Pays no commissions to brokers.
>
> Furnishes insurance at *cost* by returning all profits to assured at expiration of policies.
>
> Also insures against loss or damage by fire on all overhead lines, lamps and all other apparatus on the circuits outside of the station, under "Blanket Form" of policy.

It is well to draw special attention to the fact that this company is to be operated upon mutual insurance principles, that is, that every policy holder really becomes a stockholder in the Company in direct proportion to the amount of his premium. All stock insurance companies are organized with a certain amount of capital, and are in the business to make as much profit as possible, the less the liabilities being the greater the profits. With the mutual system, no profit is desired, as the difference between the total amount of premiums paid in, and the expenses (including salaries, sundries, and losses by fire) paid out, goes either to swell the surplus account or to be returned in the shape of dividends to the various policy holders. A mutual company has also no commissions to pay to agents or brokers, a very important factor in the running expenses when it is known that such agents for stock companies receive 25 per cent. commission. There is a large advantage also to the station manager, in the fact that the inspections are made by men trained in the electric light business who know what to propose for the elimination of danger, and who will accept no risk until suitable attention to fire protection is paid.

The Mutual system presents so many advantages in the hands of an able and experienced management that success is bound to attend, if only for the reason that every station is distinctly benefited by being insured in it, as soon as the managers fully grasp the whole inwardness of the scheme. Elswhere we print the requirements of the Electric Mutual Insurance Company for the erection and maintenance of a standard station, and we believe that the conditions are such as to arouse not only universal interest but general commendation. They will lead the way to the good, honest work of the future.

ELECTRIC TRAMWAY DATA.

THE introduction of a radical change in any long-established industry or practice is generally a slow one, for although the improvement contemplated may be perfectly apparent from calculations, business men, as a rule, prefer to wait until the correctness of such calculations have been borne out by the actual experience of their more daring fellows. In other words, the establishment of actual working data at once places a new enterprise in a favorable position for commercial exploitation. The electric railway may be said to have been a marked exception to this rule, in that its many inherent methods gained for it a hearing and acceptance long before the actual cost of its operation was clearly ascertained. By this remark it is not intended to convey the impression that those who adopted the electric railway did so on the mere assurance of success given them by the promotors of such systems, but it is worthy of emphasis that the immense development of electric railroading in this country, until recently, has been due as much to the faith of the street railway proprietors in its advantages as to any positive data for comparison. Indeed there can be no other explanation given for the existence of the large number of electric railroads at present in operation in this country,—and for the scarcity of them abroad. But this condition of affairs regarding the actual cost of operation of electric railways is fast disappearing, and we are even now in possession of data upon which reliable calculations can be based. Among the first of these we may mention the tests of Mr. O. T. Crosby, who reduced the expenses of operation to the cost per car-mile, and showed the relation of the various items which go to make up the total, including coal, attendance, real estate, machinery and line, oil and waste. These figures gave as an average 5.09 cents per car-mile for the roads in Washington, Richmond, Cleveland and Scranton. In this issue we print a most instructive analysis of the same subject, by Dr. Cary T. Hutchinson, in which are tabulated the results of a series of experiments made on a number of lines in different cities. The conclusions carried out by Dr. Hutchinson are in the main quite similar to those of Mr. Crosby, and though no actual figures are given as to the cost of operation, the relations which the various items bear to one another are of sufficient value in themselves. Some of the results obtained are highly instructive, and their application by those operating electric roads will lead to increased economy. Thus we would refer especially to the ratio of power required respectively to operate a single car and a motor car with tow. The average increase for the latter is only 33 per cent., and though the item of generating power is shown to be but 19 per cent. of the total cost of operation, attention to this item will produce additional saving. Another important and apparently anomalous fact brought out in this connection by Dr. Hutchinson's figures is, that doubling the number of cars on the line would increase but very little the cost of generating power. Lack of space prevents a more extended reference to this valuable data, but we cannot leave the subject without a passing criticism of the enormously heavy current, aggregating 80 amperes, which experience shows is taken by the motors on starting the cars. In other words, energy corresponding to 50 h. p. and more is frequently passed through the motors to bring the car from rest to motion. The strain which such a sudden development of energy must put upon a pair of motors designed to develop but half that amount cannot but be detrimental, and it speaks well for the excellence of the present construction that it successfully withstands such strains. The remedy for this evidently lies close at hand.

Copper Duties.

THE Committee on Ways and Means evidently fear that the production of copper in this country is not yet a sufficiently adult or robust industry to go alone. The McKinley tariff bill, however, assumes at least the attainment of a period of adolescence in the life of that industry by proposing a partial withdrawal of protection. The framers of the bill perhaps deem copper mining and smelting to have reached a stage of half-growth, and accordingly would cut the existing duty of four cents a pound in two, in the middle. The bill provides as follows: "Copper in plates, bars, ingots, Chili or other pigs and in other forms, not manufactured, not specially enumerated or provided for in this act, two cents per pound." A similar reduction of a moiety in existing rates on copper ores, regulus and old copper is proposed in the bill, while present rates on sheets, wire, rods and other forms of manufactured copper are retained. We do not imagine any considerable amount of grief on the part of copper miners and smelters over the proposed reduction of duty on unmanufactured copper. If they see in it any restriction tending to limit future operations in the way of combinations to control prices, they may find an offset in the meritorious provision of the McKinley bill which would permit metallurgical works to become bonded warehouses and to enter ores of dutiable metals free for treatment and subsequent export of the product, instead of paying duty on entry and getting a refund less 10 per cent. on exporting the product. Meantime it is far from certain that the McKinley bill, or anything closely resembling it, will be enacted before the adjournment of Congress. Its inconsistencies, its failure to deal adequately with the wide spreading desire for free raw materials, in short, its general insufficiency as a measure of revenue reform, evoke criticism and dissatisfaction in so many and such diverse quarters, that members of the House of Representatives are likely to find themselves in a quandary in handling it.

Effect of Current on Traction.

THE interesting record of the results obtained by Mr. O. T. Crosby on the influence of the current in increasing the adhesion between wheel and rail, which appeared in our last issue, has called forth a communication from Mr. Leo Daft, one of the pioneers in electric railroading, and the one who first drew attention to the action investigated by Mr. Crosby. Mr. Daft, it will be noted, coincides in the opinion expressed by us that the method of skidding employed by Mr. Crosby is not a wholly reliable one for this particular purpose, but he agrees in the main with Mr. Crosby as to his conclusions, so far as the present system of electric railroading is concerned. Mr. Daft's original experiments were made with heavy currents passing between wheel and rail, and their effect on the tractive adhesion between the two was unmistakable. But with the modern railway in which higher potentials and smaller currents are employed, Mr. Daft agrees that the effects are probably inappreciable. The point is, however, very interesting, and will bear further investigation.

An Electric Railway List.

We publish in this issue through the courtesy of the Thomson-Houston Electric Co., a complete list of their roads installed and under contract up to April 1. It is a remarkable showing. They have 61 roads in operation, with 665 cars and 463.56 miles of track. They have under contract 39 roads with 431 cars and 385.20 miles of track. The total is: 100 roads, 1,096 cars, 848.76 miles of track. It is to be borne in mind of course, that this magnificent exhibition of growth in a new field is that of one company. The total of American electric roads built and under contract to-day is very closely in the neighborhood of 200.

Municipal Lighting Plants.

WE publish in this issue, from Mr. M J. Francisco, the well-known president of the Rutland, Vt., Electric Light Co., a pithy discussion of the arguments presented for municipal lighting plants, and of Mr. V. Rosewater's article in particular. It is shown by Mr. Francisco that many of the figures offered by those who would have all the lighting plants owned by the local authorities, and bought or operated out of the proceeds of taxation are erroneous. We believe with him that a large number of places could be cited proving conclusively that the statements regarding municipal lighting are incorrect and untrue.

Electrical Irrigation.

THE article which appears on the following page, from Mr. W. F. Collins, opens up an entirely new field of electrical work, and we commend it to our readers for careful perusal and criticism. There will undoubtedly be work of this kind done in the near future.

ELECTRICAL IRRIGATION.

BY W. FORMAN COLLINS.

THE importance of irrigation in dry and sterile countries and districts cannot be overestimated. Vast areas now barren and worthless can, by its means, be rendered fertile and enormously enhanced in value. One drawback heretofore in carrying out work of this class, has been the great cost of construction, operation and maintenance of suitable engineering works, and especially is this the case in regions where steam power must necessarily be employed for pumping and other purposes, and where the price of coal is high. Any method by means of which irrigation on a large scale can be cheaply effected throughout the great territories of the west will be eagerly seized upon, where its field of application and usefulness is almost unlimited.

Recent statistics show that over almost one-half of this country the rain fall is not adequate for the watering and fertilization of the crops, and the lands are of an arid character. In round numbers, 1,000,000,000 acres are of this nature, and it is estimated that there is sufficient water to irrigate 120,000,000 acres. At the present time, 6,000,000 acres are under cultivation by means of canals. These arid lands comprise the finest agricultural portion of the country, and when properly irrigated and cultivated, are infinitely more productive that those of a damp and humid character. Irrigated lands in California are bringing higher prices than the first-class agricultural districts of the east.

PLAN OF ELECTRICAL IRRIGATION PLANT.

As an example of the utilization of rivers for irrigating purposes, it has been demonstrated by survey that water from the Snake river, which is a stream of large volume and forms a boundary line between Oregon and Idaho, could be stored in suitable reservoirs, fitting sites for which are situated in Idaho and Wyoming, to an amount exceeding 2,000,000 acre-feet.

In all dry climates and semi-tropical countries, where a considerable space of time intervenes between the rainfalls, irrigation is a vital and commercial necessity, even if, in carrying it out, large expenditures are required, as the richness and abundance of the crops and the intrinsic value of the land is increased many-fold.

In devising any system of irrigation, it is of the first importance that the water supply be adequate and plentiful, not only for the watering of the land, but for the needs of the stock and other uses that it may be called upon to provide for. Irrigation may have for its object either to compensate for lack of rain-fall and thus provide sufficient moisture for the support of the crop, or for the deposition of the fertilizing agents carried by the water, in which latter case large quantities may have to be employed.

The quantity of water required for irrigating purposes, depends upon the local conditions of climate, nature of soil and product to be raised, and is subject to wide variations, in accordance with the aridness of the climate. The composition and texture of the soil has an important influence on the amount of water demanded.

It is estimated that for general agricultural purposes a rainfall of from 15 to 20 inches is about the minimum requisite when the rains are not too heavy, of considerable duration and of fairly uniform occurrence, and the temperature must also be moderate. In his report to the Kansas State Board of Agriculture Colonel W. Tweeddale, C. E., proposes to employ electricity for irrigating purposes in Western Kansas. He states that it is claimed that 336 miles of irrigating ditches have been constructed in Kansas, designed to irrigate 300,000 acres of land with water procured from the Arkansas river. The amount of water, according to the estimate of the State Engineer of Colorado, required for grain crops for this amount of land, when the rainfall was nine and one half inches during the growing season, would be 3,000 cubic feet per second; while the average discharge of the Arkansas river at Pueblo during the months of May, June and July, 1888, was but 2,000 cubic feet per second, and the ordinary flow at Hutchinson in 1876 was but 1,500 cubic feet per second, being but from 66 to 50 per cent. of the requirement. From this it will be seen that the solution of the problem of irrigation for Western Kansas must be sought elsewhere. It is the universal testimony of settlers in the aforesaid region, that the soil in the river bottom, which is, for the most part, sand and gravel, is water bearing, and that the whole of the Arkansas river valley is underlaid with a vast sheet of water which can furnish unlimited and never-failing supplies of water at depths not exceeding 25 or 30 feet. The prevalent idea is, that the source of this supply is the Arkansas river, and that the completion of the immense systems of irrigating works projected, and in course of construction in Colorado, will materially affect this supply. This alarm is causeless, and no fears need be entertained of such a result, for it is evident from various considerations that the water stored in the porous soil of the bottom lands is the source of the water supply of the Arkansas river valley, rather than the flowage of the river, which, in fact, for a portion of the year, acts as a drain to the valley, and not as a supply to the under-current.

The plan proposed by Colonel Tweeddale consists in procuring the water necessary for irrigation from the underflow of ground-water by pumping from wells and distributing by means of pipes, the power for operating being distributed by electricity. The general methods of distributing water are from open ditches, by means of rills, opened and closed with shovels or hoes.

In a general way, it may be stated that, depending on the crops being raised, the more water, the larger the yield; for which reason, to insure ample and certain supply at all time, and at minimum cost, the water should be obtained from wells. These conditions will be fulfilled by the employment of pumps obtaining their supply from a system of tube wells connected to a horizontal main constituting the suction pipe of the pump. This method allows of the construction of works for the irrigation of any desired area of land, and the larger and more complete the installation, the less the cost per acre. With two sections of land as the area to be irrigated divided into units of 20 acres each, the engine and dynamos would be located at the centre of the area, and each battery of wells at the adjoining ends of two 40-acre tracts, as shown in the accompanying diagram. The motors and pumps would be portable, and the power transmitted by means of copper wires from the dynamos to the motors. The capacity of engine, dynamo, wires, wells, motors and pumps must be such as to provide for the covering of the whole area of two sections of land with one inch of water per week, which would be sufficient for ordinary agricultural purposes.

An installation for an area of 1,280 acres would consist of a 60 h. p. engine, dynamo, poles, wires, insulators, 16 batteries of wells of fifteen points each, six motors and pumps, two extra motors and pumps being provided for the purpose of allowing for moving to new stations, and thus keeping the pumps running continuously. This outfit would be ample for irrigating, on a basis of one watering per week of one inch depth of water under a head of 30 feet.

The distribution of the water may be done as in the case of that supplied from canals and ditches ; or preferably, as the water is delivered under a head, by means of a system of pipes, hydrants, hose and monitors. The cost of distribution will vary with the character of the ground and the nature of the crop, being a minimum for meadow land having a regular delivery and a maximum in the case of fruit, when, in addition to the regular system of pipes, a line of small perforated pipes is put between the rows of trees.

This method allows of the irrigation of land situated 25 feet above the pumps, and does away entirely with all labor connected with the construction and maintenance of lateral ditches and the conducting of the water over the land by means of rills.

This scheme certainly posssses many features of interest and merit and it is noteworthy that the employment of water power to operate the dynamos, where such power could be conveniently attained even if at some distance, would materialy reduce the cost of operation, as the question is one not so much of initial cost of installation of machinery, as of continual running expenses.

In many portions of the country suitable water power, now useless, is abundant, and in the near vicinity are situated tracts of land at a higher level than the water supply, and which require nothing but irrigation to render them valuable and remunerative. To effect this by natural means is impossible on account of their configuration, and here is presented a fine opportunity for employing the power of the water fall to operate dynamos and, by transmitting the current generated thereby to motors, working pumps to raise the water of the river into suitable reservoirs and conduct it by canals and ditches or piping to the arid lands.

Further, the motors destined for pump service may be employed to operate machinery for digging the ditches and the novel suggestion has been made that in some portions of the country where gold is abundant and the soil of an auriferous nature, the dirt taken out of the ditches might be washed and made to pay the expenses of digging.

As regards the cost of electrical transmission equipment, the following figures may be taken, and although probably somewhat high, are the most nearly accurate available to the writer at the present time.

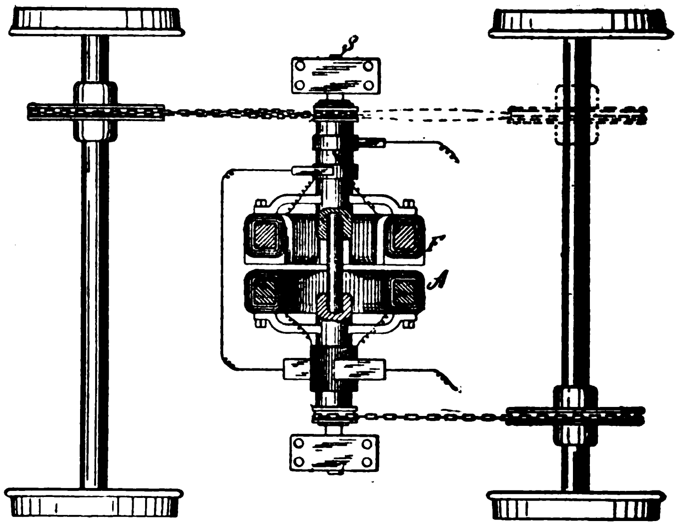
Considering a 5-mile transmission, the total cost of plant would be $160 per horse power at the motor pulley; 37,500 gallons of water per minute would be sufficient to irrigate 5,000 acres once every seven days. To raise 5,000 gallons 50 feet per minute would require 66 h. p., and figuring the efficiency of the transmission at 50 per cent., 122 h. p. would be actually needed, the cost of complete installation being about $20,000.

The many advantages of irrigation are only too apparent. In California lands now worth from $3 to $10 per acre, without opportunity or reasonable hope of irrigation, command $50 to $200 per acre when water is brought to them. The yields are far greater, the crops of finer quality and entirely independent of drouth, certain and sure, regardless of seasons, thereby benefiting the whole country and the community living on and drawing their incomes therefrom.

The application of electrical power for irrigation is as yet a virgin soil, and needs only the intellect and energy of those skilled in the art to grow and increase with rapid strides, whilst it is a field which offers almost endless possibilities for the utilization of that intangible power which is more flexible, more readily transmitted, more economical, more reliable and more easily handled and controlled than all other known sources of energy.

PERRET'S ELECTRIC RAILWAY MOTOR.

It has been pointed out on several occasions that much of the inconvenience attached to the employment of gears in electric railway work could be avoided by the employment of a motor running at a lower speed ; andthere are some who have not yet given up the hope that the sprocket and chain can be successfully applied for the transmission of power from motor to axle. Acting on this idea evidently, Mr. Frank A. Perret, of Brooklyn, N. Y., has recently brought out an arrangement which is illustrated in the accompanying engraving. The idea embodied by Mr. Perret's design is to obtain a means of independently driving the axles of the car by the use of one motor only, and secondly to reduce the difference in speed between the driving pinions of the motor and the axles of the vehicle so that less intermediate gearing will be required. At the same time it is intended to retain the moderately high speed of the armature, as related to the field magnet, which is necessary to obtain high efficiency. For this purpose it will be noted that the armature A. and field F. are independently mounted on sleeves which encircle the stationary shaft S. and the arrangement is such that both the field and the armature revolve, each in opposite directions. The power developed is transmitted to the axles by means of a sprocket and chain.



Perret's Electric Railway Motor.

The practical effect of this arrangement is that the actual speed of either motor of the system is only half what it would be were the other motor stationary, and the ratio of the gearing to the wheels is correspondingly reduced, while at the same time the relative speed between the two is the same as if one were stationary and the other revolved. It will also be noted that while one motor is employed, both axles are driven.

"INCREASED ADHESION" BY CURRENT.

BY LEO DAFT.

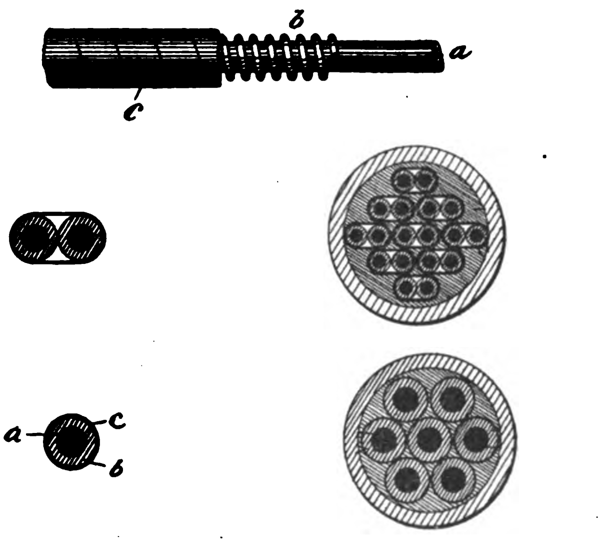
In reading the very interesting communication by Mr. Crosby in the last issue of The Electrical Engineer, I recalled many similar attempts to prove increased adhesion by current which invariably failed to demonstrate anything but the fallacy of experiments depending upon current observations in skidding an anchored car.

Not only is it almost impossible to make trustworthy readings under conditions involving such spasmodic changes, but the gradual "seating" of the wheel, due to the heating of the rail by friction at the small point of contact, frequently increases its tractive value more than I have observed with current alone.

While it must be admitted that the first experiment described in these pages in 1883[1] was unsatisfactory from a practical standpoint, the later tests made during my connection with the company bearing my name, when a small car containing one man was made to ascend a gradually increasing gradient until the possible limit due to gravity alone was enormously exceeded, seem to leave no positive doubt that with large currents the effect is a most potent factor. Subsequent experiments and a long series of observations in actual work have, however, resulted in so far modifying my views as to lead to the conclusion that with the comparatively high potentials now generally employed the currents are not large enough to produce a very marked effect, and, therefore, while I do not consider Mr. Crosby's experiments at all conclusive, he is not far wrong in his deduction.

BARRETT'S TELEGRAPH AND TELEPHONE CONDUCTOR.

Although it is well known that air presents the lowest specific inductive capacity of all dielectrics, its nature is such, of course, that except for aerial lines, it has not in the past been employed as insulating material for electric conductors. When wires are made up in the form of cables, evidently, some more substantial insulator is required, and the variety of these is very great. But the difference in the effects obtained respectively with aerial and underground lines, and noted more particularly in the telephone service, is such as to greatly impair efficiency where cables are employed, the limit of speaking distance being rapidly approached. It is with the idea of increasing the transmitting power, as it were, of a wire placed in a cable, that Mr. John A. Barrett, of Brooklyn, N. Y., has recently brought out a conductor in which, he has sought to embody, as far as possible, air as insulating material, in contra-distinction to the usual method in which the wire is entirely surrounded by some form of solid or liquid insulating material.



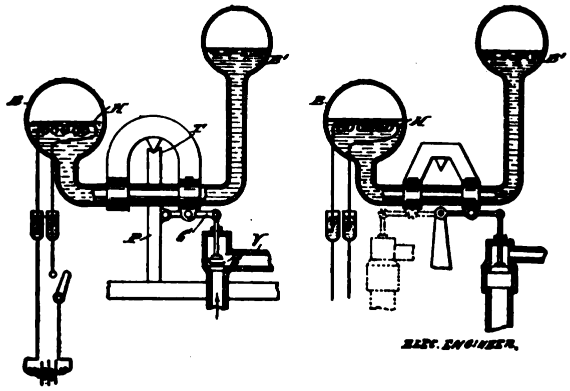
Figs. 1, 2, 3, 4 and 5—Barrett's New Conductor.

This idea has been carried out in the manner shown in the accompanying illustration, Fig. 1, in which, as will be seen, the conductor *a* is wound about with a wrapping of hard cord, which has a low, hygroscopic quality, and of the thickness suitable for the purpose required. About this wrapping of cord one or more thicknesses of paper are closely wrapped, making the whole smooth and round. After the wires have been so prepared, they are made up in cable form, as shown in two methods in Figs. 2, 3, 4 and 5.

After being properly bunched and covered with lead, the insulating material is applied, but in such a manner that it merely surrounds the paper covering of the wire, which is sufficiently dense to prevent the penetration of the insulating material to the conductor itself, and which thus always remains surrounded by a layer of air. Cables made in this fashion show a greatly reduced static capacity, and telephonic transmission through them is considerably facilitated.

THOMSON'S ELECTRIC VALVE CONTROLLER.

Our readers will recall the very ingenious form of electric meter which was brought out by Professor Elihu Thomson some time ago, in which the amount of current passing through a circuit was registered by the oscillation of a pivoted arrangement, the balance of which was disturbed successively by the displacement of a liquid caused by its vaporization, due to the heating of a conductor placed within it. It is evident that this device may be adapted for a variety of purposes, and it has more recently been carried out by Professor Thomson for the operation and controlling of valves. The accompanying illustrations show very clearly how this is accomplished. In Fig. 1, B and B^{1} are two bulbs connected by tubing and filled with an easily vaporized liquid. A conductor, such as a platinum wire, H. is placed within one of the bulbs B, and its terminals dipped into the mercury cups placed in the circuit which is controlled by a switch. It is evident, therefore, that upon closing the circuit of the coil H there will be generated in chamber B a vapor, which, as it cannot escape, will press down upon the surface of the liquid and force it towards the chamber B. This disturbes the balance of the two bulbs and the pivoted body swings over, tipping the end B^{1} down and closing the valve G. By placing the bulb B^{1} on a higher level than that of B, the emptying of the bulb B^{1} is insured when the current is taken off the coil H. Fig. 2 shows a modification of the apparatus in which the valve is opened by the tipping of the pivoted bulbs. By means of this device, evidently, a valve can be controlled at any distance by the mere touch of a push button.



Thomson's Valve Controller.

WHAT ELECTRICITY WOULD HAVE SAVED.

In a lecture on "The Electrical Transmission of Energy," recently delivered in Cambridge, Mass., Captain Eugene Griffin, U. S. A., gave statistics showing that in New England there have been only five deaths by electricity in ten years, and in the same time there have been 5,241 deaths from steam railroads. He also stated that if the West End Railway Co., of Boston, had used electricity as motive power solely last year, the company would have made a saving of $1,000,000 in money and 100 years of time to the persons using it.

AN EXPOSE OF MUNICIPAL ELECTRIC LIGHTING FIGURES.

BY M. J. FRANCISCO.

AMERICA is the birth-place of the commercially successful electric light, and in five years the public demand has necessitated the investment of over two hundred millions of dollars to supply the electric lights required. From the experimental plant of 10 lights the business has increased to 275,000 arc lamps and over 3,000,000 incandescent lamps burning nightly in the United States. This large industry and vast investment has put millions of money into circulation and given employment to over 250,000 men. The benefit to many places cannot be calculated in dollars, while the additional security offered the citizens and the prevention of crime where electric lights are used is of far greater value.

Notwithstanding the benefits derived there has been engendered a spirit of opposition and a seeming attempt to assail the electric light interests of this country by false and deceptive statements as well as invidious comparisons intended to prejudice the general public. The electric light companies have been held up as monopolies, yet with all their extortion the records show that the average return or dividend received by these bloated monopolies has been only about two per cent., thus showing that they have proved of greater benefit to the public than to their stockholders.

Attempts have been made to antagonize the municipalities and the electric interests, and efforts in many cases to force the price of electric lights below the actual cost of producing them. In all these raids the fact that the companies have so largely contributed, as many of them have, to the material development, the commercial prosperity and social progress of the communities or places in which they exist is ignored.

Some party who desires a chance to dispose of a plant or secure a position raises the cry that the municipality should own and furnish the lights; the plea being that it can be done for so much less money.

Can a city secure labor or buy materials or dynamos any cheaper than a corporation, and when as shown the profits or dividends realized by the electric light companies have only averaged two per cent., how can a municipality pay four or six per cent. interest on its bonds and expect to save money by owning the plant and assuming the liabilities and losses which experience shows are sure to occur?

Hardly a week passes without some article appearing in the papers purporting to show the cost of the electric lights and the great saving to municipalities by owning the plant; the latest and one that shows an utter ignorance of the facts or experience in the business appears in the New York *Independent*.[1] This article has display head lines saying:—"Cost of Electric Lights. Boston pays $180 per lamp, and Ypsilanti only $24." By this statement the reader is led to believe that Boston is being swindled, and as a proof the cost of lights in Ypsilanti, where the city owns the plant, is given as a comparison.

What are the facts? Boston is furnished with lights all night and every night in the year, and the company producing the same have to use steam power with coal $4 or $5 per ton, besides having to pay the city heavy taxes.

Ypsilanti uses water power costing nothing; burns the lights only 20 nights each month until midnight, and uses the buildings belonging to the water-works of the city, and salaries and expenses of men to run the lights are charged to the water department.

In the same article, Topeka, Kan., is cited as the Mecca where lights only cost the city $72 per year for all night.

Topeka purchased an electric light plant of 184 lights for $50,000 and the company or parties who sold the plant to the city, represented that the cost of each lamp would be $6 per month or $72 per year. This amount is given in the article referred to as the cost of lights in Topeka. The city officials have found by actual experience, and so report, that the cost of running the lights is $11 per month or $132 per year for each lamp. The mayor states it as his opinion that it would have been much cheaper in the end for the city to have contracted with the local electric light company for the lights.

Dunkirk, N. Y., is quoted as burning 55 arc lights all night every night, at a cost of only $36.50 per year; about $3 per month. The cost for the month of October as reported was $225.28, not including superintendent, engineers' and firemen's salaries, interest on plant, depreciation and repairs, as these are paid by the water department. Add to this the salaries of superintendent, engineer, fireman, interest, depreciation, repairs and taxes, which an electric light company would have to pay and which the city does pay, but charges to another department, and the cost is $625 per month for 55 lamps, or over $11 per month per lamp and $132 per year.

Chicago is cited as a sample of municipal lighting, and where it only costs the city $65.60 per year. But J. B. Barrett, the superintendent, writes that this price does not include any expenses, such as taxes, water rents, interest on investment, insurance, repairs or renewals in general.

Any electric light company would be glad to furnish lights at the price claimed it costs Chicago, if all their expenses, repairs and such disbursements as are specified were paid by some other corporation.

The *Independent* writer, Mr. V. Rosewater, gives $105.13 as the average price paid per year by cities, to private parties, for lights. This is $26.87 less than it costs the City of Topeka to furnish their own lights.

These are samples of the comparisons that are being made by the advocates of municipal lighting, and it is surprising that a man who claims to be connected with Johns Hopkins University should be willing to attach his name to a communication containing so many statements that are manifestly incorrect, misleading and unjust to the electric lighting interests of the country.

In connection with municipal lighting, why did not Mr. Rosewater refer to the largest municipal lighting plant in this country and the operations of the great gas trust of Philadelphia, where the city lost $3,500,000 in six years in owning and operating its own lights; and notwithstanding the city now owns the gas plant, they are contracting with electric light companies to light their streets and paying according to the *Independent* statement, $177 per year, for each lamp. Here is a city that has tried municipal lighting for years and abandoned it, and hires local electric light companies to furnish the lights, and pays more than three times as much according to this writer as it costs other cities to produce them.

Which is the best authority, actual experience, or the theory of parties with no practical knowledge of the business?

AN ELECTRIC INSECT TRAP.

It is told of Mr. Edison that in his early days, when his thoughts had not yet been directed towards the fields which have since proved so prolific of results, his inventive genius, ever restless from the beginning, was called into play to devise a method for removing some troublesome insects which had for a long time infested the telegraph operating room in which his desk was situated. For this purpose two strips of metal were placed along the wall about one-eighth of an inch apart and insulated from each other, but connected to the opposite poles of the main line battery. By the application of a suitable bait the insects were induced to cross the gap between the two parallel strips, and it is needless to say that the instant they made contact between the strips they dropped lifeless to the floor. We are reminded of this by the issuance of a recent U. S. patent to Mr. François Scherer, of Paris, France, in which the inventor seeks the destruction of the unwary insect by placing within a cage-like structure an electric lamp and surrounding it with a gauze-like frame, the alternate bars of which are connected respectively to the opposite poles of an electric battery. It presents the somewhat anomalous feature that the insect to be destroyed meets with its fate on the outside of the trap instead of the inside, as is usually the case.

---

[1] The ELECTRICAL ENGINEER, April 9, p. 214.

SWINBURNE'S ALTERNATING CURRENT MOTOR.

Among those who have given considerable attention to the design of alternating current apparatus during the past few years is Mr. James Swinburne, of London, whose theory in regard to the construction of transformers is embodied in the "hedge-hog" type of transformer with open magnetic circuit. Recently Mr. Swinburne has devoted his attention to the development of alternating current motors and as a result there has been lately issued to him in England a patent for a new type of alternating motor.

This machine is designed so that at any instant its back electromotive force is just less than the electromotive force on its terminals by enough to cause the armature current needed to give the power. At no load such a motor should give a back electromotive force which at any instant is almost exactly equal to the terminal electromotive force. At full load the field is weakened enough to let the necessary current pass, so that the motor does not need to lag much and weaken its field by the reaction of its armature current.

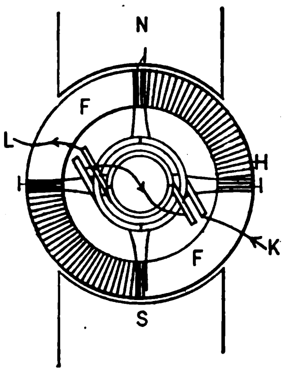

Fig. 1.

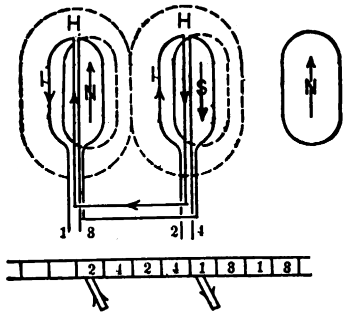

Fig. 3.

Various ways of exciting this machine, both separately and by self-excitation are employed by Mr. Swinburne. In one form the exciting circuits are so arranged that at no load the field excitation gives a back electromotive force approximately equal to the electromotive force in the mains. If it has very nearly the same back electromotive force, the motor at no load becomes co-phasedly synchronized and takes just enough current to drive it and give power for excitation. It is found best, however, to allow a margin so that the back electromotive force is a little less than the main electromotive force. The motor then leads a little at no load. This slight lead allows a small armature current to pass which strengthens the field by reaction. This increases the excitation, as the exciting coils in the armature come under the influence of the same pole pieces. This again increases the back electromotive force, so that neither the lead nor the armature current becomes excessive. If too much margin is allowed, the motor will lead too much, and will take a large current at no load, which is wasteful.

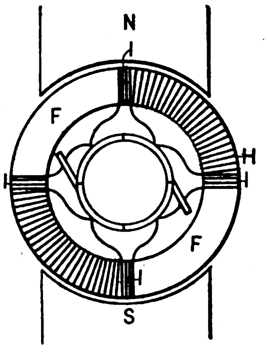

Fig. 2.

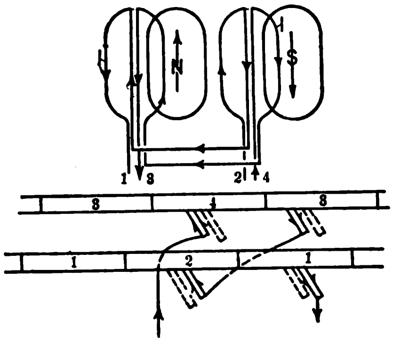

Fig. 4

When load is put on, the motor begins to lag. The armature current then reacts on the fields and weakens them; this weakens the field excitation, as the exciting coils are influenced by the same field magnets, and the field can thus be weakened enough without much lag. The field excitation is so designed that the iron is not highly magnetized. On the other hand it must not be too sensitive.

The inventor has carried out his ideas in a variety of forms. One of these is illustrated diagrammatically in

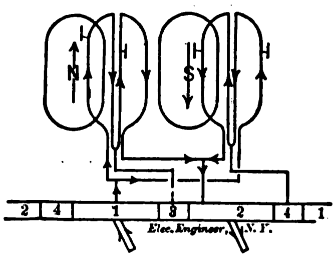

Fig 5.

Figs. 1 and 2, in which a ring armature F is employed, a two-pole machine being shown for the sake of simplicity. H H are the active or main coils of the machine, which are connected to the connecting rings as usual, and I I are the exciting coils of the armature. The brushes are in connection with the field magnets by the leads K L. If the armature is stationary and the field rotates, the brushes are connected to the armature coils, and the sections of the commutator to the field circuit. In Fig. 2, the exciting coils are connected up as in the Gramme ring. This arrangement demands four brushes and two sections when the armature is stationary and the field rotates.

Fig. 3 is a diagram of the exciting armature coils in a machine whose armature is made of a flat strip without an iron core. The main coils H H and pole pieces N S N are shown with parallel sides, instead of radial, for the sake of simplicity. The main armature coils are shown as dotted flat oval coils H H. They are connected to collecting rings in the usual way. Inside the main coils, in the space at present generally left vacant, are pairs of exciting coils shown as full lines I I. These coils are more clearly distinguished in Figs. 4 and 5 where the main coils H H are omitted. N S N are diagrammatic representations of the pole pieces in the figures. The arrows on the pole pieces show the direction they induce a current when a conductor passes from right to left. The arrows in the coil circuits show the direction of the induced exciting currents. In Fig. 3 two pair of coils are shown. Each pair is connected in series. 1, 2, are the ends of one pair, and 3, 4 the ends of the other pair. In an actual machine instead of two

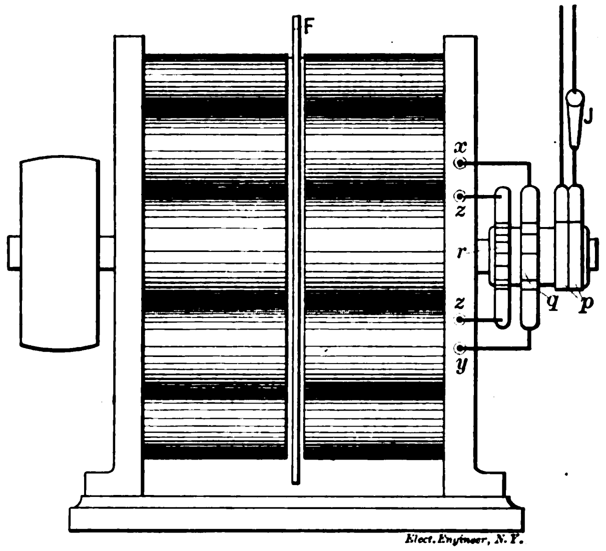

Fig. 6.

pairs there are two sets of correspondingly situated coils, coupled, in series.

Below the diagrams of the coils in Figs. 3, 4 and 5, are diagrams of the commutator sections, and the brushes, which are connected with the field magnet circuit. The numbers on the commutator sections show which ends of the coils I I are connected to them. In Fig. 3 each set of active coils is in circuit when it has an electromotive force induced in it, the other set being out of circuit. Fig. 4 is analogous, roughly, to Fig. 1. There are two commutators and two pairs of brushes, and the sets of coils are in series. For starting the motor the brushes are shifted to the dotted positions, and the main current is passed through both the field and armature circuit; and when speed is attained, the connections are altered. Fig. 5 shows an arrangement somewhat analogous to that of Fig. 2.

The machine, which is designed both as a motor and a generator is shown complete in Fig. 6. Here p represents the collector for the main armature current, and q is the commutator in series with the armature current, for weakening the field in case of a motor, and strengthening it in the case of generator.

Here also, x y are the terminals of the main or series field coils, and r is the commutator in connection with the armature exciting coils, for exciting the field magnets; z z represent the terminals of the field circuit connected to it. To start the machine as a motor the brushes of the series circuit are shifted so that the series wire magnetizes instead of demagnetizing. The main current is then turned on through a safety resistance. When the machine has reached its normal speed the brushes are shifted to their proper position, and the load is put on.

A "ROSEWATER" VIEW OF MUNICIPAL LIGHTING.

BY ALLEN R. FOOTE.

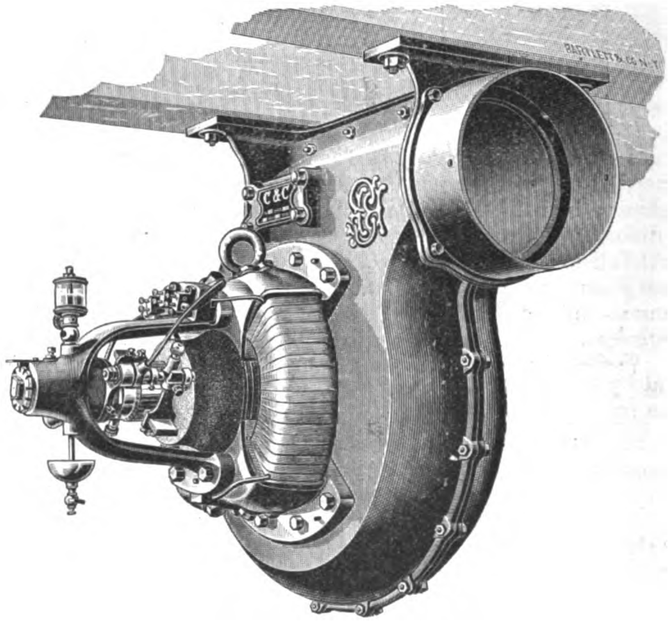
THE people of the United States for the past few weeks have witnessed a stupendous exhibition of unutilized genius. An article has been furnished for publication, originally to the *Independent*, that has appeared as a reprint in a number of journals, purporting to give the cost of lighting in a large number of cities. The intention of the article is to show how much more capable politicians are, as managers of an electric general station, than those men who have their capital, livelihood and reputations at risk in the management of such undertakings. It is no wonder that such a discovery should attract universal attention.

In this article, the cost price given for all-night lighting in nine cities owning the plants, averages $53.80 per lamp per year. It is ordinarily estimated that one arc light requiring about forty-five volts and nine amperes, consumes one horse power of steam at the engine. In an article appearing in the *Buffalo Express*, April 3, it is stated that a horse power of steam costs $39 per year in Rochester, N. Y., $46 in Lockport, N. Y., and $45 in Baltimore, Md., making an average of $43.33 per year. At this cost for steam power the difference is $10.47, to cover all other expenses of operating the electric light plants in the nine cities named. The carbons will cost $5.40 per lamp per year. This will leave those cities but $5.07 per lamp per year for all other expenses, including depreciation and the interest on the investment.

I believe that the central station companies of the United States can make no better investment of money than to employ these "literary fellers" to teach them how to run their business. They must have some secret not possessed by those practically engaged in the work. For no man in the actual management of a plant has been able to keep his expenses within their limits. I suggest that the National Electric Light Association employ Mr. Rosewater to instruct its members how to operate arc lights at a cost of $53.80 per lamp per year. If he will guarantee to do this, I think that every company in the country would take a membership in the Association to get the benefit of the instruction. By dividing the "gate money" with him, Mr. Rosewater would have an income of about $10,000 per year from the operation. With that amount I am sure he could buy a lease of absence from Johns Hopkins University, and have a good wide margin for profit left. This profit, I presume, he would at once cover into the treasury of some charitable institution, as he preaches the gospel of "no profit for lighting plants." He certainly cannot object to the expectation that Rosewater would not retain a profit for operating the "Rosewater" lighting plant for the illumination of the National Electric Light Association.

VENTILATION ON BOARD SHIP.

THE ventilation of ships has in the last few years received considerable attention, and especially since the introduction of electric lighting on ships has placed at the disposal of the engineer a ready means of solving what has heretofore been a practically unsolved problem, so far as general ventilation of a ship was concerned. With the dynamo current available, its application to the driving of electric motors attached to fans and blowers was a natural step. The electric blower can be put anywhere, as the wire carrying to it the current which furnishes the motive power, can be introduced into one place as easily as into another, and this application of the electric current provides at once a most convenient and in some cases the only means of thoroughly renovating and purifying the air.



ELECTRIC BLOWER ON U. S. MEN-OF-WAR.

The orifice of discharge in a blower is smaller in proportion to the amount of air passing through than that of any other machine for creating a forced draught of air, and this especially recommends it for ships and in places where the discharge current of air has to be carried a distance in pipes, as the pipes required are small and no special provision need be made beforehand to allow space for them. Any blower such as would be ordinarily required for this purpose must be small and not obtrusive to the eye; and hung on the ceiling, it is out of the way. By a small pipe the discharged air can be carried to the deck or any convenient point without taking room that might be needed for other purposes.

As an example of this new and important class of work we illustrate a blower directly connected to a C. & C. electric motor. This blower has been placed by Messrs. Cramp & Sons' Ship and Engine Building Co. on the U. S. cruiser "Baltimore." It is type No. 4 and discharges 1,425 cubic feet of air per minute. Fastened to the ceiling of the dynamo room it completely changes the air of the room once every two minutes, discharging it at a distant point through a small pipe. The entire machine is so compact that it takes up no space that could be used for anything else and does its work so noiselessly that a person standing near cannot tell without the closest observation whether it is running or not.

The ease with which these blowers can be set up and connected to the dynamos, without requiring any shafting, belting or other contrivance except the small wire, has already brought them to the attention of ship builders, and both the cruisers "Charleston" and "San Francisco" launched on the California coast recently, as well as the "Philadelphia" from Cramp's Yards, have had blowers placed in their engine rooms.

WIGHTMAN'S CONTROLLER FOR RAILWAY MOTORS.

It is well known that in starting a series wound electric motor some means must be provided to prevent an abnormal rush of current through the armature, as, being stationary, it can afford by itself no opposition or counter electromotive force. There is thus required either the placing of a resistance in circuit for starting, or an arrangement for creating sufficient self-induction in the armature to prevent excessive current. On the other hand, when the current through the motor is ruptured suddenly, the self-induction which takes place is manifested by an energetic flash at the point of rupture. In the case of the electric motor the field magnets are specially liable to have their insulation punctured by the high potential generated by the self-induction. This "kick" of the field magnets, as it is sometimes called, has been sought to be overcome by placing immediately upon the core of the magnet a copper sheath in the shape of a spool upon which the insulated wire of the winding is coiled. This sheath constitutes a short-circuited conductor about the magnet, and its action is to retard, or slow down, the rate at which the field can lose its magnetism, and hence is able largely to prevent the sudden rise of potential formerly experienced.

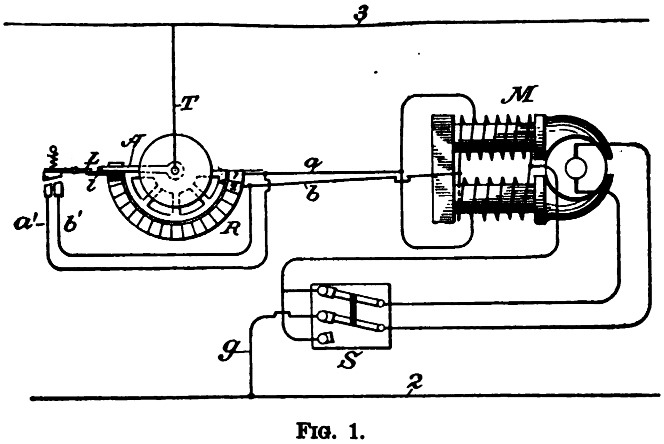


FIG. 1.

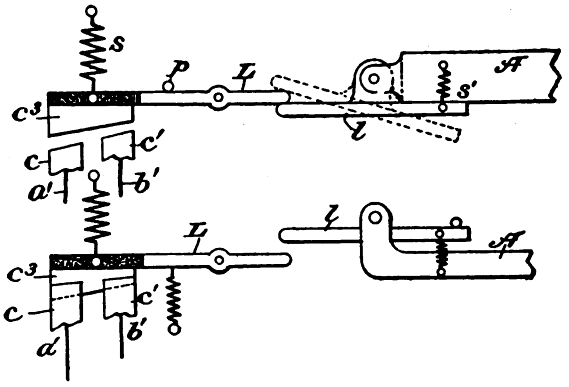
But the presence of this short-circuited conductor when the current is first turned on the motor will be detrimental because it is then desirable that the field magnet should oppose a strong counter electromotive force, and hence in this case the sheath is rather a detriment than an aid.

In order to retain the advantages of the close-circuited conductor, but at the same time to avoid the inconvenience just pointed out, Mr. Merle J. Wightman has designed a method by which the short-circuited conductor may be opened or closed so that the operator on an electric car, for instance, can have the short circuit closed at the time the circuit is broken, and open when he wishes to start the car. For this purpose Mr. Wightman employs what is known as a biased switch; that is, one in which a spring or weight normally tends to hold in one of two positions. The manner in which this is carried out is shown in the diagram, Fig. 1, which illustrates the motor and circuits; Fig. 2 showing an enlarged view of the open circuiting switch.



FIGS. 2 AND 3.

As will be seen, the section of the field magnet coil included between wires *a b* is used as the short-circuited conductor on the field, which takes up the extra current ensuing on breaking the circuit. The short circuit for this section is completed by a circuit-breaker and closer. *c c'* are two contacts of this device joined to wires *a b*, while c^3 is the circuit-closing plate that, by making contact with both plates *c c'*, closes the short circuit. The circuit closer is held open normally by a spring *s* against a stop *p*.

The lever L of the circuit-closer and breaker is engaged by a trip-lever *l*, pivoted on the arm A and provided with a spring *s'*, that normally holds it in the position shown in full lines in Fig. 2. These parts are so arranged that at the instant before the main switch opens the circuit the trip-lever *l* with the circuit-closing lever L, and will close the short circuit and keep the same closed until the main switch has moved sufficiently far to put out any arc that might follow on rupture of the circuit. After this point is passed the trip-lever *l* escapes by the circuit-closing lever, so that on return of the lever A for the purpose of again closing the circuit the trip-lever *l* slips by the lever L, in the manner indicated by the dotted lines, Fig. 2.

The circuit through the motor is from conductor T through switch A, rheostat R, line *b*, fields of motor in multiple, reversing switch S, armature of the motor, back to reversing switch S, and out at *g*.

The operation of the apparatus is as follows: Normally the section of winding connected to *a b* performs its ordinary function of energizing the field magnet, its short circuit at the switch *c c'* being open. If the main switch A be turned to open the circuit of the motor the section of field winding will be short-circuited at the instant of rupture of the connection through the motor. The strong induced currents circulating in this winding will have the effect of retarding or cutting down the heavy extra current and preventing destructive sparking or generation of dangerous potential in the field windings. After this operation the circuit-closing device opens the short circuit for the section of field-coil, and maintains the same open until a repetition of the operation just described. As the switch is turned back to close the circuit through the motor, the short-circuit-closer for the section of field-winding maintains its open position, as just explained; hence the field-magnet coils may exercise freely the self-induction, which will prevent a sudden rush of current through the motor and consequent injury at the time of starting the motor. As the arm A is turned, the resistance is gradually decreased and the motor speed gradually increased, until, finally, the switch passes to the contact *l*, thereby cutting out a section of the field-winding and still further increasing the speed beyond the capacity of the rheostat to do so by diminution of rheostatic resistance.

In the engraving, Fig. 3, another form of this switch is illustrated, in which the arrangement above described is reversed, the arrangement being such that the switch normally keeps the short circuit closed, instead of open.

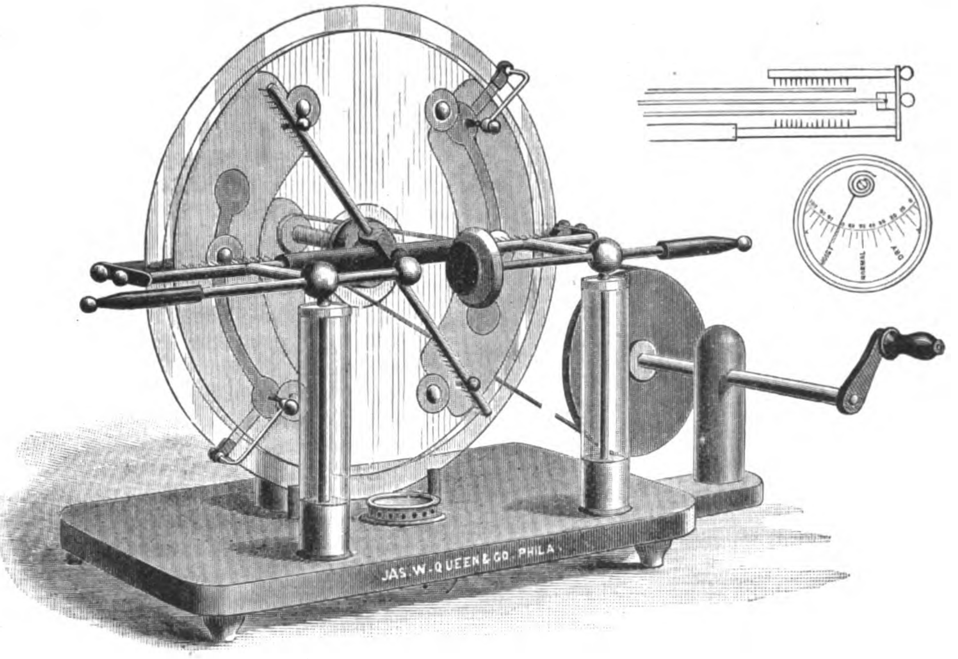
A NEW TRIPLE-PLATE TOEPLER-HOLTZ MACHINE.

Probably the machine most generally employed in the study of static electricity at the present time is the Holtz or some of its modifications, and among these the Toepler-Holtz machine has risen to considerable prominence. The latter machine was introduced into the United States in the year 1880 by the late Joseph J. Walton, of Messrs. Queen & Co., of Philadelphia, and has since then been variously modified from its original design. Still further improvements have recently been made which have resulted in a practically new type of machine.

The new machine which is illustrated in the accompanying engraving, as its name indicates, is a three-plate machine; it is not, however, the same thing as the machine usually spoken of as the "double revolving plate machine," although it does have two revolving plates. The latter machine is simply an ordinary Toepler-Holtz machine doubled; *i. e.*, with a revolving plate behind the fixed plate, exactly like the one in front, and acting in exactly the same manner.

In the new form, the additional plate is not like the front revolving plate, nor does it act in at all the same way. The third and additional plate is here a perfectly plain glass plate, mounted upon the same axis as the usual revolving plate, and placed behind the fixed plate. Its *modus operandi* is, like many other points in the theory of the Holtz machine, not entirely understood, although there is no doubt that much of the increased efficiency obtained by its use is due to the screening effects it has upon the other plates, that is, to the leakage that is prevented by its presence. There is also supposed to be a considerable generation of electricity by friction of the plain plate and the air. Undoubtedly many other causes also tend to increased effects of possibly even greater importance than those just mentioned.

Another improvement that is made in this machine is the form of the electrode which is used. This is made of a metallic disk two inches, or more, in diameter and hollow, so as to have very gradually rounded edges, thus preventing any leakage at the edges. Over this disk, separated from it by about an eighth of an inch, and nearer the other electrode, is fastened a thin disk of vulcanized rubber, about half an inch less in diameter. This rubber disk plays the part of the rubber sheet sometimes held between the electrodes before a spark can pass. It can be used upon either one or both electrodes.



A New Triple-Plate Toepler-Holtz Machine.

The advantage of this new form of machine becomes especially marked during moist weather. At such times ordinary frictional machines will not work at all, and hence all older text-books direct that electrical experiments must be performed during January and February, when the weather is clear and dry. With the Toepler-Holtz machine, as now known, this requirement has not been so rigid, although such machines are not always to be trusted during damp seasons, as lecturers have found out to their sorrow.

In testing two of these machines last September, Professor Wm. A. Anthony, in order to determine whether the extra plate gave any increased effect to the machine, set up both machines and arranged them so that they both could be revolved by means of one crank, and so that they both ran at the same speed, and then adjusted the terminals until the sparks occurred with about the same frequency in both. He then removed the combs from one of them so that the third plate would have no effect in the development of electricity, and found that the frequency of sparks on that machine was very much less than on the other. He repeated this several times with the same result, and tried the same experiment on the other machine; that is, leaving the combs on the first machine, he removed them from the second, when that one was found to give considerably less electricity than the first. From this it was evident that the addition of the third plate very much increases the rate of discharge, and, as nearly as could be determined by this rough experiment, about double, the rate.

Professor Anthony also found the machine to work uniformly well in all weathers. As our illustration shows, the machine is provided with a hygometric gauge, which indicates the amount of moisture in the atmosphere. These machines, we may add, are now being made in various sizes by Messrs. Queen & Co.

TESTU TELEPHONE.

This instrument, says the *Bulletin Internationale*, looks almost like a watch, and is chiefly interesting because it has been adopted on the government telephone service. In the interior of the case, and screwed to the under side, are two concentric bowls of soft iron, superposed and each with a large edge carrying six sloping pieces disposed symmetrically. They are each furnished with a winding giving a reverse polarity, the outer bowl being a south pole and the inner a north pole. The two coils are connected in series, and have a resistance of about 55 ohms. The vibrating membrane is placed above the two electromagnets and forms the upper lid of the box. The inventor of this apparatus, M. Testu, is special agent of the Administration of Posts and Telegraphs.

ELECTRIC TRAMWAY DATA.

BY CARY T. HUTCHINSON, PH. D.

In this paper I purpose giving a short account of measurements made by me for the Sprague company, and published with their consent, on several electric tramways; the measurements are chiefly electrical, but in some few cases engine tests were made. The data refers entirely to Sprague roads.

The same instruments were taken from place to place; they were two Weston voltmeters reading to 600 volts; two Weston ammeters reading to 100 amperes; a Wheatstone bridge set with 20 cells of battery; Tabor indicator, tachometer, speed indicator, etc. The electrical instruments had been calibrated just before starting out. I expected to have an ammeter reading to 300 at least, but it was not ready in time; hence for station readings the station ammeters had to be used.

All the roads are of the overhead, underrunning trolley system, with main conductors parallel to trolley wire along the sidewalk, connection being made at short intervals; the roads will be referred to as "A." "B," "C." "D" and "E."

A brief description of the character of the roads will be useful. Road A is divided into two parts by an "incline plane," about 1,000 feet long, having an inclination of about 35 per cent.; this incline is operated by a cable. The cars run through the lower part of the city, the business part, to the incline; here they are lifted by a carriage on the incline to the top of the hills and continue on out into the residence portion of the city.

When these tests were made the incline was not working, owing to an accident some weeks before; hence the road was running in two separate sections, the lower and the upper. The lower end has about 1.03 mile, and the upper 1.92 mile of double track. The rails are used here as return, there being no copper wire parallel with the track. This road is very uneven; there are very few level parts, and one grade as high as 15 per cent. for a short distance, and with almost all grades up to this.

POWER HOUSE:—

The power house is at the head of the incline, nearly at the middle point of the line.

It contains:—

Two tubular boilers 16" x 66" with 54 flues; heating surface, 1,089 square feet; grate surface, 22.7 square feet. These are rated at 90 h. p. at 90 lbs. pressure. They supply steam to the engine used for the cable as well as for the dynamo engines.

Two engines, the first a Ball 16' x 16", running at 240 revolutions, of 150 h. p.; the second a Greenwald (Brown) 18" x 42", running at 70 revolutions, of 150 h. p. Each of these engines drive two 50-kilowatt Edison shunt dynamos, 500 volts, at 845 revolutions. The slow-speed engine is belted to a countershaft; the high-speed directly to the dynamos. The Ball engine is held only as a reserve.

Usually 20 cars are run, some with tow cars; but at this time only ten were in use on account of the accident to the incline. The station is operated about 19 hours per day; the car mileage is 107 per day, and the duty of cars about 230 car hours per day.

Here, the engines were indicated, and coal weighed, first using the Ball and then the Greenwald engine, reading of currents and E. M. F. being taken at the same time for a run of 8½ hours; the time was chosen so as to give as nearly as could be judged an average result; this is, the loads carried would average for the time about the same as if the tests had been taken for the entire day's run. Car readings and grade readings also were taken.

December 20. Greenwald Engine.

Readings taken from 9.30 A. M. to 6 P. M.=8.5 hours. Current and E. M. F. readings every minute. Engine cards every half hour.

Average (for time) number of cars	8.26
Mean E. H. P. from station readings	54.6
Mean E. H. P. from station readings, per car	6.6
Mean I. H. P.	67.2
Mean I. H. P., per car	8.1
Coal burned	2,283 lbs.
Coal burned per I. H. P., per hour	3.96 lbs.

December 22. Same arrangements, except Ball engine.

Readings from 9.25 A. M. to 6 P. M.—8,6 hours.

Same number cars	8.26
Mean E. H. P. in station	56.2
Mean E. H. P. in station, per car	6.8
Mean I. H. P.	66.3
Mean I. H. P., per car	8.0
Coal burned	3,835 lbs.
Coal burned per I. H. P., per hour	4.98 lbs.

The average number of passengers per trip was not more than six to seven.

The friction card taken from the Ball engine turning both dynamos with the field circuits closed was 21.5 h. p.

READINGS ON GRADES:—

No. 1. Mean grade 6 per cent., 965 feet long, with maximum of 10 per cent. for 80 feet and 15 per cent. for 90 feet.

Speed, 5 miles per hour; 10 passengers.

Power required	21.2 h. p.

No. 2. Same repeated.

Power	23. h. p.

No. 3. Straight 4 per cent. grade for 2,472 feet, perfectly regular.

Power	18 h. p.

Insulation resistance 25,000 ohms for the entire system, about six miles of pole; this is .15 megohm-miles.

COST:—

I am not at liberty to give the actual cost of operation for many reasons, but shall give here certain ratios which may be instructive.

By "cost per car-mile" I mean the cost of "generating the power," plus cost of keeping cars and line in repairs, *i. e.*, maintenance, plus cost of motormen and conductors, reduced to a car-mile basis. This excludes office expenses, rent, interest, depreciation other than repairs, salaries of clerical force, insurance, and, in fact, all general expenses of this nature. Cost of "generating power" or "central station" includes fuel, oil, waste, water, and attendance, *i. e.*, engineers, oilers, firemen, and all force about station.

Central Station Cost, Maintenance, Carmen = "Cost" per Car-Mile. The carmen form the very large part of this difference; other things are practically very small. Sometimes an employee, as an "electrician," works on the line and motors, as well as in the power house, so that, strictly, his time should be charged partly to one account and partly to another. This is not practicable, and so such a one is charged entirely to the power house.

Maintenance includes the entire cost of keeping cars and line in repair, *i. e.*, materials and wages.

On road "A.," then, putting the cost per car-mile at 100, the distribution is as follows:

Carmen	71.5
Maintenance	1.8
Generating power	26.7
	100.

Further the power house item is divided into

Labor	20.
Fuel	5.9
Oil, water and waste	.8
Generating power, total	26.7

ROAD "B."

This road is almost pefectly level; no grades worthy of the name exist. It is divided into two branches, which keep together for about 2.5 miles and then diverge. On one route there is about 5.5 miles and on the other about 4.94 of double track.

POWER HOUSE:—

The power house is placed at almost the middle point of the line; the equipment consists of the following:

Boilers.—Seven tubular boilers, 18″ x 6″, 70 flues; heating surface, 1,488 square feet; grate surface, 33 square feet, rated 150 h. p.; 90 lbs. pressure. These boilers all have Murphy mechanical stokers.

Engines.—Three Armington & Sims, 18⅛″ x 18″, 200 revolutions; 250 h. p.; three A. & S., 14½″ x 15″, 260 revolutions; 125 h. p. Each engine is belted directly to two dynamos.

Dynamos.—Six 80-kilowatt, compound wound, with carbon brushes, two to each large engine. Six 40-kilowatt, shunt; two to each 125 h. p. engine. These last are to be compounded.

The station runs 24 hours per day. From 1 to 6 A. M.; only two cars are on the line; the rest of the time the average is about 30. Motor cars draw tow cars about two-thirds of the time; for example, during November, car No. 142 ran 3,098 miles, of which 2,247 miles was with a tow car; this was about the average. From this a car runs 103 miles a day; train, 75 miles per day. Speed from 6 to 9 miles per hour; average about 8.

CAR READINGS:—

No. 1. Motor car with tow, 16-foot cars. Round trip about 11 miles; 40 passengers; 30 per cent. of readings were zero, *i. e.*, current off; speed 7.2 miles per hour; mean starting current, 95 amperes; maximum starting current, 120 amperes.

Power on car.............................. 8.5 H. P.

No. 2. Same motor car but no tow; round trip 11.7 miles; speed 7.6 per hour; 18 passengers; 40 stops; 33 per cent. of readings, zero; mean starting current, 80 amperes; maximum, 100 amperes.

Power on car.............................. 6.17 H. P.

From tests made by the company's engineers, engine cards and electrical readings being taken every half hour, they find:

Mean average, E. H. P	276
Mean average, I. H. P	360
Ratio, $\frac{\text{E. H. P}}{\text{I. H. P}}$	77 per cent.

The number of cars running at the different hours of the day was not noted by them.

The insulation resistance was 6.9 megohm-miles for about 15 miles of poles; separate feeder circuits gave 2.9, 1.4 and 10 megohm-miles; the low figure was for a line running through trees.

COST:—

Since motor power cars tow a large part of the time, there can be no reduction to a motor car mile, or to a train mile simply; but,

Average number of motor cars per day	23.4
Train mileage	75
Motor car mileage	103

The motors tow for 73 per cent. of the entire time; this is:

23.4 x .73, average number of trains	17.1
23.4 x .27, average number of motors alone	6.3

Further, if X be the total cost per train mile, and Y be the total cost per motor car-mile (without tow), then, $\frac{17.1\,X + 6.3\,Y}{23.4}$ is the cost per car-mile run by the motor, regardless of towing.

This figure will be meant when "cost per car-mile" simply is used, and is to be distinguished from "cost per train-mile" and "cost per motor car-mile."

If the "cost per car-mile" be 100, then the distribution is as follows:

Carmen	73.7
Maintenance	14.
Generating power	12.3
Total	100.

And of the cost of the power house:

Labor	6.4
Fuel	4.2
Oil, waste, water, etc	1.7
Generating power, total	12.3

RATIO OF COST ON TRAIN TO COST ON MOTOR CAR:—

The cost of conductors and motormen is in the ratio, $\frac{\text{Train}}{\text{Motor car}} = 1.47$; this item is 73.7 per cent. of the total.

The power required for a train is, say, 1.4 times that for the motor car; but attendance at the power house is not increased, and oil is increased inappreciably; about the only increase is in fuel, and fuel constitutes about ⅓ of the power house expense.

Therefore, the ratio of the cost of power, $\frac{\text{Train}}{\text{Motor}} = (\frac{2}{3} + \frac{1}{3} \times 1.4) = 1.13$. This item is 12.3 per cent. of the total. Repairs are alike for both, and are 14 per cent. of the total. We have then:

$$\text{Ratio of total cost, } \frac{\text{Train}}{\text{Motor Car}} = .74 \times 1.47 + 1.13 \times .12 + .14.$$

$$\text{That is, } \frac{X}{Y} = 1.37.$$

ROAD "C."

The road here is entirely single track with turnouts about 4 miles long; there are many grades, some of 7 or 8 per cent; in fact, the entire road is up and down-hill. The road is in the form of an L, with the power house at the junction; one branch has a return copper conductor; the other uses the rails connected at intervals to buried earth plates for the return.

POWER HOUSE:—

Boilers.—Two tubular 18′ x 6′; 68 4″ tubes. Heating surface, 1,450 square feet; grate surface, 33 square feet; rated at 150 h. p.

Engines.—Three Ball 16″ x 16″, 240 revolutions, 150 h. p., belted directly to dynamos.

Dynamos.—Six 50-kilowatt Edison; four are shunt, but are soon to be compounded.

Nine or ten cars run constantly, and both boilers are used with two engines and four dynamos. They burn about 6.7 tons of coal per day of 16 hours. Round trip about 8 miles. Car mileage 105 per day.

Car Readings.—Readings every 30 seconds; number of passengers, 18; number of stops, 30; mean starting current, 47 amperes; power, 7.74 h p.

POWER ON GRADES:—

1.38 per cent.	—650 feet	10 H. P.	Ave. 11.9
1.4 "	—900 "	12.4	
1.5 "	—1,600 "	13.4	
3.25 "	—800 "	15.	
3.8 "	—800 "	17.3	Ave. 18.5
3.8 "	—1,200 "	19.8	

The load in all cases was about 9,000 to 10,000 lbs., and the speed from 7 miles per hour to 5 on grades.

The insulation resistance was 3.2 megohm-miles, with about 8 miles of poles. The resistance of the copper overhead conductor and return underground by copper wire and rails of the section fitted this way is 2.25 ohms.

Calculated resistance of outgoing circuit.	1.38 ohms.
Return	.87 "

The distance was two miles. This was the only place at which I succeeded in making this measurement; there was always some interference by extraneous currents, giving large deflection when battery circuit was open.

I have not been able to get the cost of operating this line.

ROAD "D."

The town here is entirely flat; there is a main line with six branches tapping the main line at various points of its length and running to both sides of it. The power house is at one end of the line.

POWER HOUSE:—

Boilers.—Two tubular 78″ x 16′; 104,2″ tubes. Heating surface, 1,013 square feet. Grate surface, 33 square feet.

Engines.—Two Ball, 16″ x 16″; 250 revolutions; 150 h. p.

Dynamos.—Four 50-kilowatt Edison shunt wound.

About 17 cars are equipped and 14 of them run for 18 hours; one engine and one pair of dynamos are used from 6 A. M to 3 P. M., the other set from 3 P. M. to 12 midnight.

The speed was about 6 miles per hour; there was no towing; the car-mileage is 105 per day.

Car Readings.—Readings every 30 seconds; 8 passengers, 30 stops; mean starting current, 75 amperes; power, 8.62 h. p.

GRADE READINGS :—

Flying start, 9.5 per cent for 775 feet	23.7 H. P.
Still start, 9.5 per cent. for 775 feet	25.7
Load about	9,000 lbs.

ENGINE TESTS :—

Cards were taken at half-hour intervals from 2 to 7 P. M., to include the heavy load of the evening.

Maximum card	124 I. H. P.
Minimum card	44 "
Mean for 5 hours	86.4 "
Friction of engine and two dynamos, circuits open	13.4 I. H. P.

The above gives :—

Average power per car	6.17 I. H. P.

The load here does not vary so much as usual owing to the large number of cars run to the engine; I have seen the line current as high as 850 amperes, *i. e.*, a 150 h. p. engine doing 215 h. p. of electrical work, to say nothing of friction load.

The insulation was about 4 megohm-miles.

COST :—

Taking the cost per car-mile as	100
we have the following :	
Carmen	67
Maintenance	18
Generating power	15
	100

And of the power house expenses :

Labor	7.3
Fuel	5.2
Oil, waste, etc	2.5
Generating power, total	15.0

ROAD "E."

There are no grades on the main line of this road; it has about 2.8 miles of double track. Eight motor cars run on an average; but for about an hour in the afternoon, ten motor cars run, six of them with tow cars. The car-mileage is 110.

POWER HOUSE :—

Two Babcock & Wilcox, 150 h. p. boilers, 64 tubes, 4″ by 18′; heating surface, 1,404 square feet; grate surface, 35 square feet. There are two 18″ by 42″ Corliss condensing engines of 150 h. p., and two 80-kilowatt shunt wound Edison dynamos.

The engines are belted to a countershaft fitted with clutches so that either or both engines can run either or both dynamos; usually one engine is used with two dynamos turning, only one supplying current; but during the time of heaviest load both dynamos are in circuit. Neither ground wire nor earth plates is used; the return is made entirely by the rails connected to each other by copper bonds.

Here coal was measured, engine cards taken every 15 minutes, and station readings every 2½ minutes from 5.40 A. M. to 11.30 P. M., that is, for the entire day's run. The results are :

Average I. H. P	66.5
Average E. H. P	52.
Average number of cars	8.
I. H. P., per car	8.3
E. H. P., per car	6.5
Shafting with two dynamos, circuits open, but fields made	24.6 H. P.
Shafting alone	15.6 "
Leaving for one dynamo	4.5 "

Time of test, 17.7 hours.

Coal	5,350 lbs.
Coal per I. H. P., per hour	4.54 "
Coal per square foot grate per hour	8.6 "

CAR READINGS :—

Cars all 16-foot; motor car weighs nearly 10,000 lbs.; trail car, 5,300.

Without trail car: About 7 stops; 14 passengers.

Mean starting current, 75 amperes; 33 per cent. of the readings zeros; E. H. P., 8.1

With trail car : About 9 stops; 20 passengers.

Mean starting current, 80 amperes; 30 per cent. of the readings zeros; E. H. P., 10.3.

Ratio of power, train to motor car, 1.27.

Both of the above are the mean of a number of trips.

The insulation was .5 megohm-miles for 8 miles of poles.

COST :—

The amount of towing is inconsiderable, only 7 car hours out of 141; so that it is taken into account only in the wages of carmen.

Taking the cost per car-mile as equal to	100
we have	
Carmen	65·5
Maintenance	12.7
Generating power	21.8
	100.

And of the power house cost:

Labor	10.
Fuel	10.
Oil, waste, etc	1.8
Generating power, total	21.8

Same measurements of the time required to stop and start the cars taken here, of which the results are given below; the timing was done by a man on the car with a stop watch.

The motor car weighed 10,000 lbs.; the tow car, 5,300.

FOR MOTOR CAR:—

A. Time car remained stationary.

Average of 77 readings	7.1 secs.
Maximum	22. "
Minimum	3. "

The readings are all close to the mean; the 22 is unique, and no other is near it.

B. Time for starting car to 2 poles' distance, that is, 250 feet.

Average of 128 readings	22 secs.
Maximum	30 "
Minimum	12 "

All very close to the mean.

C. The time for throwing off current to stop :

Average of 95 readings	12.8 secs.
Maximum	21. "
Minimum	5. "

All very close to the mean; the distances varied from 100 to 120 feet.

D. Time of running from pole to pole, that is, 125 feet; full speed.

Average of 208 readings	6.25 secs.	—13.7 miles per hour.
Maximum	7 "	12.2 " "
Minimum	5 "	17. " "

Same for motor with tow.

A. Average of 145 readings	8.25 secs.
Maximum	45. "
Minimum	2. "

No readings between 20 and 45 seconds; the readings are fairly close to the mean.

B. Average of 132 readings..............23½ secs.
Maximum..............................30 "
Minimum..............................18 "

All close to the mean.

C. Average of 111 readings.............. 11,5 secs.
Maximum.............................. 23. "
Minimum.............................. 7. "

All close to the mean; average distance 150 to 190 feet.

D. Not taken.

The following tables give most of the above results and some deductions from them:

TABLE I.

	1	2	3	4	5	6	7	8	9	10	11
Roads.	Average number of cars running.	Car Mileage.	Mean I. H. P. in station, per car.	Mean I. H. P. per car on the line.	Mean E. H. P. in station, per car.	E. H. P. on car, no tow.	E. H. P. on car, with tow.	Ratio of power; motor car + tow to motor car.	Mean starting current in amperes.	H. P. hours per car-mile.	Insulation in megohm-miles.
A.	8.24	107	8.1	5.4	6.7				82	.96	.15
B.	23.4	103				6.2	8.5	1.38	80	.84	6.9
C.	9	105				7.7			47	1.15	3.2
D.	14	105	6.2	5.2		8.6			75	1.44	.4
E.	8	110	8.3	5.3	6.5	8.1	10.3	1.27	80	1.05	.5
Ave		106	7.5	5.3	6.6	7.6	9.4	1.33	72	1.09	2.2

TABLE II.

Power on grades—average:

A.	4 per cent	17.9 H. P.
A.	6 "	22.1 "
C.	1.43 "	11.9 "
C.	3.25 "	15. "
C.	3.8 "	18.5 "
D.	9.5 "	24.7 "

TABLE III.

COST:—

Average of all the four roads in per cent.:—

Carmen	69.5
Maintenance	11.5
Generating power	19.
	100.0

Of the power house:—

Labor	11.0
Fuel	6.3
Oil, waste, etc	1.7
	19.0

Column No. 4 in Table I is the first that calls for comment. These figures are obtained from deducting the friction card from the mean I. H. P. and dividing by the number of cars. The result is roughly constant, which of course means nothing more than that the power on the car is nearly constant in spite of the varied conditions of the road, and should show in the electrical measurements as well as in the I. H. P.; for "D" and "E" the car measurements are nearly the same, viz., 8.1 and 8.6 h. p. On the other hand, taking the average power from station readings, "A" and "E" agree, viz., 6.7 and 6.5 h. p.; so the values tie up, so to speak. The electrical readings do not however, agree as closely as the mechanical.

The car readings were all taken at 30-second intervals; it was thought that this would be clear enough to give a good average, but it is not. I believe that no readings taken at equal intervals, that is, such intervals as are practicable, will give a fair average in all cases. The only right way is to have a recording meter, a wattmeter, if possible, or otherwise an ammeter, which will give a continuous record. Next to this the best plan is to to take readings at every change of the current, the time being noted; then plot the readings and integrate the curve. With 30-second readings I have got smaller power in cases when it obviously should be greater.

The chief reason for the discrepancy between car and station readings is probably the much too great frequency with which the high readings are caught; it takes the current from three to five seconds to fall from the maximum to its normal value; yet almost every high reading seems to be caught. Further, no readings are taken when car is standing at its termini; besides, the station ammeters have heavy moving parts, and hence do not respond to sudden changes.

Column 10, giving the h. p. hours per car-mile is calculated from the average of the station readings in the case of "A" and "E," together with the average car-mileage and average time of running. But in the case where no station readings were taken, the actual time of a round trip is taken; for "D," however, the car value had to be used with the average mileage, on account of the numerous delays on the run; this case shows the greatest divergence from the mean.

The mean starting current is low for "C," because there the old style Sprague motors are used which have about double the resistance of the present style. It will be noticed that these figures for starting current are much higher than those given in Mr. O. T. Crosby's recent paper, the reason being that he used an Ayrton & Perry spring ammeter; this instrument is not dead beat, and the first reading taken is far from the greatest actually attained.

The insulation is abundantly high in all cases, remembering the low line resistance; besides only 30 volts was used in measuring it, while 500 is the ordinary E. M. F. There seems to be no special difficulty in keeping the insulation high enough for this kind of work; .01 megohm-mile would be ample for a minimum figure.

The power for grades does not vary just as one might expect. For instance, for the 3.8 per cent. grade greater power is taken than for the 4 per cent.; but it must be remembered that these are far different roads with entirely different conditions of track.

The ratios of the various items in the cost of a road are rather instructive; the figure given for maintenance is, I believe, nearly correct as an average; the value for "A" is abnormally low, while for "B" it is equally high. The small part of the cost chargeable to fuel is noteworthy; doubling the number of cars on the line would involve in an ordinary station very little increase in cost of generating power; labor probably being not at all, and oil, etc., only slightly, increased.

In conclusion I may say that the roads here reported on are not selected as the best by any means, but were chosen simply as falling into a convenient arrangement of routes; one in particular is an old road, with all old style motors.

EFFECT OF ATMOSPHERIC ELECTRICITY ON TELEGRAPH LINES.

For a number of years exhaustive information on electricity in storms, with special regard to the influence of atmospheric electricity on the telegraph service and on telegraph apparatus, has been collected by the Imperial Telegraph Department, Berlin. At present, 900 telegraph offices have instructions to keep a record of the course, duration, direction, etc., of storms. From the observations made, it appears that, while not altogether free from the influence of atmospheric electricity, such influence is materially smaller in the case of underground wires compared with wires above ground. In 1888, 338 interruptions from storms were observed in underground wires, and in the above ground wires 2,375 cases of injury were reported. In regard to town telephone wires, it is worthy of remark that, notwithstanding the violence of several of the storms in the towns having a telephone system, the accidents from lightning compared with former years were strikingly few, and the assumption does not, therefore, appear to be without justification that the wires spread over the roofs affords effective protection in equalizing atmospheric electricity.

INDUCTION AND INTERFERENCE WITH TELEPHONE SERVICE FROM A TELEPHONIC STANDPOINT.[1]

BY W. J. DENVER.
